A14.26 Ignition

A14.26.1 Ignition sources

There is a small amount of information on the distribution of ignition sources, much of it for offshore installations.

A study by the Fire Protection Association (1974) of ignition sources for large fires in the chemical and petroleum industries in Great Britain in 1971–73 gave the data shown in Table 2.11. There were 79 fires of which 23 were solid and 10 unknown, the other 46 being gas, vapour or liquid.

Ignition sources for process industry fire and explosions reported to the HSE in the year 1987–88 have been analyzed by A.W. Cox, Ang and Lees (1990). Separate analyses are given for normal, closed process plants and for plants and activities with open surfaces, etc. The former sets have been given in Table 16.46 and the latter are shown in Table A14.53.

Offshore ignition sources have been given for fires and explosions in the Gulf of Mexico (GoM) and in the Norwegian North Sea (NNS) in reports by workers at Det Norske Veritas (Sofyanos, 1981; Forsth, 1981a,b, 1983).

Forsth (1983) has given the data shown in Table 16.47 for ignition sources in these two locations. The number of accidents considered was for the GoM was 326 over the period 1956–81 and for the NNS 133 over an unspecified period.

Table A14.52 *Estimated frequency of releases on ammonia installations and carriers (after Baldock, 1980; reproduced by permission of the American Institution of Chemical Engineers)*

Incident	*No. of incidents*	*Estimated frequency*
Major failure of storage vessel	2	1 in 6 × 10^4 vessel-year
Major release from storage vessel	1	1 in 10^4 storage area-year
Serious release on plant	12	1 in 2000 plant-year
Release on refrigerator plant	15	1 in 10^5 plant-year
Release at transfer point

A14.26.2 Ignition probability

A discussion of the probability of ignition of gas and liquid releases is given in Chapter 16. The account there utilizes data on blowouts on offshore installations given by Dahl *et al.* (1983). A fuller tabulation of these data is shown in Table A14.54.

Impact failure	37	41.1
Human error	32	35.6
External events	14	15.6
Service failure	1	1.1

[a] Of the 131 accidents, causes of 90 were known.

A14.28 Fires

A14.28.1 Process plant fires

A survey of the frequency of fires in industry in Britain has been reported by Rutstein and Clarke (1979). For the chemical and allied industries (Standard Industrial Classification 5) they correlate the probability of fire per year with the floor space of the building using a function of the form

$$P = aB^c \qquad [A14.28.1]$$

where B is the floor space (m^2), P the probability of fire over 1 year, a is a constant and c an index. They give the following data:

	Probability of fire over 1 year	
	All buildings	*Process buildings*
Probability function	$P = 0.017B^{0.27}$	$P = 0.069B^{0.46}$
Probability for 1500 m^2 building	0.12	0.21

A survey of the major safety incidents has been conducted by Williams, G.P. (1999). Eighty-nine ammonia plants during the period 1994–96 have one fire every 14.2 months on average, which is slightly better then previously reported value of 14.6 months.

A14.28.2 Petroleum industry fires

Information on the frequency of fires in the petroleum industry in the United States is given in the annual series Reported Fire Losses in the Petroleum Industry by the API. The fires reported are those involving losses greater than \$2500. The fires losses for the period 1982–85 are shown in Table A14.55.

A14.28.3 Refinery fires

Data on the frequency of refinery fires are given in Table A14.57. The API fire loss reports also give a breakdown of the fire losses. For 1985 the sizes of fire by loss were

Size of loss (1000\$)	*No. of fires*
2.5–100	65
100–1000	37
>1000	7

The frequency of refinery fires may be estimated from these data and from the number of refineries given in Section A14.11. The *First Canvey Report* gives frequency of fire in a refinery = 0.1 fires/year

A14.28.4 Pump fires

Estimates of the frequency of pump fires have been given by Kletz (1971) and are shown in Table A16.55.

N.M. Wallace and David (1985) have described a study in Esso on mechanical seals, in which losses due to fires from pump failures were apportioned as follows:

Seal failure	54%
Bearing or shaft failure	36%
Unknown	10%

A14.28.5 Storage tank fires

Information on the frequency of fires on storage tanks in the petroleum industry in the United States is given in the annual series *Reported Fire Losses in the Petroleum Industry* by the API. The fires reported are those involving losses greater than \$2500. The storage tank fire losses for the period 1982–85 are shown in Table A14.56.

For fires in fixed roof storage tanks for hydrocarbons Kletz (1971) states that based on data from more than over 500 tanks over a period of 20 years the frequency of a tank fire or explosion is once in 883 tank-year.

His estimate of the factor by which the frequency of fire or explosion may be reduced by the use of inerting is 10.

A14.29 Explosions

A14.29.1 Furnace explosions

Data on the distribution of causes of furnace explosions has been given by Ostroot (1972). The numbers of incidents listed are

Cause of explosion	*Furnace firing*	
	Gas	*Oil*
Inadequate purge	55	12
Delayed ignition	42	81
Incorrect fuel–air ratio	19	5

In the discussion to the paper Kletz (1972c) said that his company reckoned on a frequency of explosion of 1 in 25 furnace-year. Ostroot quoted for his company a figure of about 1 in 100, or even 1 in 1000 furnace-year.

A14.29.2 Vapour cloud explosions

Data on vapour cloud explosions have been given by Davenport (1977, 1983).

For vapour cloud explosions at fixed installations Davenport (1983) records some 35 cases over the period 1962–82 inclusive. The location of these explosions is

United States	19
Western Europe	10
Other	6

If it is assumed that there were at risk in the United States and Western Europe over this period some 10,000 chemical/petrochemical plants, major refinery units, LPG storages and natural gas plants, then

$$\text{Frequency of vapour cloud explosion} = 29/(21 \times 10{,}000) = 1.4 \times 10^{-4} \text{ explosions/year}$$

Information on the distribution of leak sources in vapor cloud explosions is given in Table A14.49.

Further data on vapour cloud explosions are given in Chapter 17.

A14.30 Transport

Failure data for transport are given in Chapter 23 and Appendix 17.

A total of 185 accidents involving natural gas (gaseous) were surveyed with 179 from the Major Hazard Incident Data Service database (Montiel *et al.*, 1996), of which 131 (70.8%) is transportation related. These 131 accidents during transportation are further analysed, and Tables A14.57 and A14.58 give a summary of their findings.

A14.31 External Events

A14.31.1 Aircraft crash

Information on the probability of a potentially damaging accident due to an aircraft crash at various reactor sites is given in the *Rasmussen Report* (table III 6–4). The highest probability quoted is 1×10^{-6}/year for a crash at a site located 5 miles from an airport with 40,000 air carrier and 40,000 naval flight movements per year. The assumed target area is 0.01 mile^2 for larger aircraft and 0.005 mile^2 for smaller ones.

The impact of the aircraft would not necessarily cause damage within the containment. In fact the estimated probability that such damage would occur given impact is less than 1 in 100.

Other accounts of the risk of aircraft crash are those of D.W. Phillips (1981 SRD R198) and Marriott (1987).

Appendix 15 Earthquakes

Contents

An earthquake is one of the principal natural hazards from which process plants world-wide are at risk. Some account is therefore necessary of the seismic design of plants and the assessment of seismic hazard to plants.

Accounts of earthquakes are given in *Seismicity of the Earth and Associated Phenomena* by Gutenberg and Richter (1954), *Elementary Seismology* by Richter (1958), *Introduction to Seismology* by Bath (1979), *Earthquakes and the Urban Environment* by Berlin (1980), *Earthquakes* by Eiby (1980), *An Introduction to the Theory of Seismology* by Bullen and Bolt (1985) and *Earthquakes* by Bolt (1988). Treatments of earthquake engineering, most of which give some coverage of seismology, include *Dynamics of Bases and Foundations* by Barkan (1962), *Earthquake Engineering* by Wiegel (1970), *Fundamentals of Earthquake Engineering* by Newmark and Rosenbleuth (1971), *Earthquake Resistant Design* by Dowrick (1977, 1987), *Ground Motion and Engineering Seismology* by Cakmak (1987) and *Manual of Seismic Design* by Stratta (1987). UK conditions are dealt with in *Earthquake Engineering in Britain* by the Institution of Civil Engineers (1985) and by Lilwall (1976) and Alderson (1982 SRD R246, 1985).

It is proper to recognize also the large amount of work done on seismicity and seismic engineering in Japan.

Earthquake engineering is a specialist discipline. The account given here is limited to an elementary introduction.

Selected references on earthquakes, earthquake-resistant design and earthquake hazard assessment are given in Table A15.1

A15.1 Earthquake Geophysics

A15.1.1 Earth structure

The structure of the earth is illustrated in Figure A15.1 and is approximately as follows: a crust 30 km thick, a mantle 2900 km thick and a core of 3470 km radius, giving a total radius of 6370 km. The core has an inner core of 1400 km radius.

The crust exhibits two layers. In the lower of these layers the velocity of seismic waves is rather higher. The interface between the two is known as the Conrad discontinuity. Likewise, the mantle is divided into the upper and lower mantles. The crust and the upper mantle are termed the lithosphere. Other discontinuities are the Mohorovicic discontinuity at the boundary of the crust and the mantle, and the Gutenberg discontinuity at the boundary of the mantle and the core.

A15.1.2 Crustal strain and elastic rebound

The earth's crust has a degree of elasticity and when subject to stress due to the earth's forces it undergoes crustal strain. This property is the basis of the elastic rebound theory of Reid, which provides one explanation of the way in which earthquakes occur. Reid suggests that 'the crust,

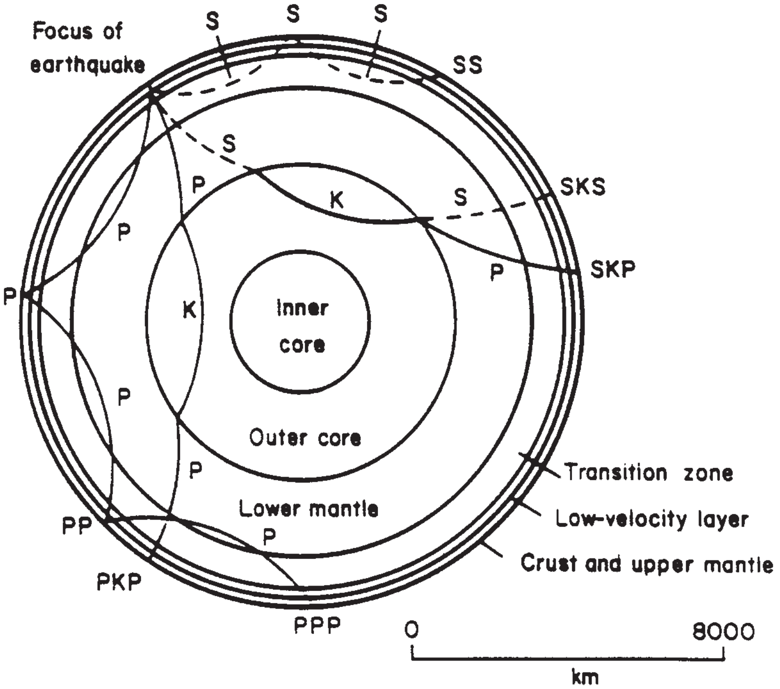

Figure A15.1 *The structure of the earth and passage of seismic waves through it (US Geological Survey, 1975)*

in many parts of the earth, is being slowly displaced, and the difference between displacements in neighbouring regions sets up elastic strains, which may become greater than the rock can endure. A rupture then takes place, and the strained rock rebounds under its own elastic stresses, until the strain is largely or wholly relieved'.

A15.1.3 Plate tectonics, faults and fault creep

In some regions earthquakes are associated with faulting of the earth, while in others there appears to be little apparent correlation between earthquakes and structural features.

Earthquakes are frequently associated with faulting of the earth. There has been debate, however, as to whether the faults have caused the earthquakes or the earthquakes the faults. The latter viewpoint has been argued by Evison (1963).

A fault in the crust may be caused by tension, compression or shear. A normal fault, in which slip occurs between one block and another, is usually considered to be the result of tension and a reverse fault, in which one block is thrust below another, the result of compression or thrust. These two types of fault are also termed dip-slip faults. The slip plane is characterized by the angle of dip, or angle of the plane to the horizontal; an angle of dip close to 90° corresponds to a nearly vertical slip plane. In a shear fault the relative movement of the two blocks is predominantly horizontal. This type is also termed a strike-slip, or transcurrent, fault. There are also oblique slip faults in which there is a combination of vertical and horizontal movement.

As a result of displacement, the ground in a zone extending out from a fault can become permanently deformed. The disturbed zone, or shatter zone, can be up to 1 km wide. The magnitude of displacements is discussed by Berlin, who mentions cases of a 14.4 m vertical displacement, or uplift, in Alaska and of a 4.9 m horizontal displacement in California; there is a 6.1 m horizontal displacement reported for the 1906 San Francisco earthquake but this is subject to some doubt.

The build-up of strain in the crust may be relaxed by a much more gradual movement of the crust, or fault creep. This process, which may be continuous or episodic, does not generate earthquake waves. An account is given by Berlin.

In some regions there are faults that are associated with recent seismic activity, or active faults. Perhaps the best known is the San Andreas fault in California. This fault is a strike-slip fault, or, viewed on a finer scale, a system of strike-slip faults. There are often lesser faults associated with the main fault as branch faults or as subsidiary faults, joining the main fault at oblique angles and sometimes in echelon along it.

There are some regions which are very much more prone to earthquakes than others. One explanation for this is given by the theory of continental drift, and of plate tectonics, according to which the earth's lithosphere is divided into a number of rigid plates that move relative to each other. Earthquakes are much more frequent at these interfaces. The Pacific rim is the most striking example, but there are a number of others.

There are a number of definitions of what constitutes an active fault. For the siting of nuclear power plants in the United States, the NRC considers a fault to be active if there has been movement at least once in last 35,000 years. Other definitions are discussed by Berlin (1980).

As stated earlier, however, earthquakes do also occur in regions where there is no apparent correlation with active fault structures.

A15.1.4 Focus and epicentre

The origin of an earthquake is termed the focus, or hypocentre, and the point on the earth's surface directly above the focus the epicentre.

Earthquakes are classified as shallow focus (focus depth <70 km), intermediate focus (depth 70–300 km) and deep focus (depth >300 km).

A15.1.5 Seismic waves

During an earthquake waves pass through the earth and impart motion to the ground. These waves are elastic in that the rocks through which they pass then return to their original shapes and positions.

There are two broad types of wave: body waves and surface waves. Body waves are classified as primary, or P, waves and secondary, or S, waves. A P wave is a longitudinal or compression wave, is analogous to a sound wave and has a velocity of some 8 km/s. An S wave is a transverse or shear wave, is analogous to electromagnetic waves and has a velocity of some 4.5 km/s. The passage of P and S waves is illustrated in Figure A15.1. Both P and S waves can undergo reflection. Reflection can occur at the earth's surface or at a boundary such as that between the mantle and the core. Refraction can occur through the core. On reflection both types of wave can be transformed to the other type, that is, a P wave to an S wave, or vice versa.

The notation used for P and S waves is illustrated in Figure A15.1. A P wave travelling directly from the focus to the point of measurement without reflection is denoted as P, one undergoing one reflection at the surface PP and one undergoing two reflections at the surface PPP. A P wave undergoing one reflection at the core is denoted as PcP. The corresponding notation for S waves is S, SS and SSS for a wave with zero, one and two surface reflections and ScS for a wave with one core reflection. There are also hybrid waves such as PS, PSS, PPS, PSP; SP, SPP, SSP, SPS; PcS and ScP.

Both P and S waves can undergo refraction through the earth's core. In the core itself there is a difference between P and S waves: an S wave cannot pass through the core. However, the wave leaving the core can be either a P wave or an S wave; in the latter case this is due to transformation at the core boundary. Hence, an S wave can enter the core, undergoing transformation to a P wave on entry and further transformation to an S wave on exit, and then travel on as an S wave again. The principal refractions through the core are denoted as PKP, PKS, SKP and SKS (K for Kern in German). There are also more complex waves such as PKKP (refraction–reflection–refraction in the core) and PKPPKP (refraction in core–reflection at surface–refraction in core).

The distance between the focus and the point of measurement is generally expressed in degrees rather than kilometres. A degree corresponds to about 111 km.

There is a limiting angle of about 103° at which a P wave is reflected from the core. At any angle greater than this the wave is refracted through the core. The effect is to create between an angle of about 103° and one of about 142° a 'shadow zone' to which waves do not penetrate.

The other main type of wave is surface waves. Surface waves, long waves or L waves, travel round the surface of the earth rather than through the interior. They are classified as Love, or L_Q, waves and Rayleigh, or L_R, waves. Love waves have a horizontal but no vertical component, Rayleigh waves have both horizontal and vertical components. A Rayleigh wave is generally described as having a retrograde elliptical motion. Both types of wave travel more slowly than S waves, with the Rayleigh wave slower than the Love wave.

L waves may travel round the earth several times and generate ground movement with amplitudes of about 1 mm. They have a typical period of 10–20 s. They contain large amounts of energy but do relatively little damage on account of the long period. Often an earthquake is 'heard before felt'. Sounds like a low rumble can be generated by the faster P waves, while the ground shaking is due to the larger amplitude but slower S waves.

A15.1.6 Seismic measurements

An instrument for the recording of the ground motion caused by an earthquake is known as a seismometer and the record that it produces a seismogram.

Measurements may be made of any of the three main time-domain parameters: displacement, velocity and acceleration.

The measurement of ground motion is well developed and records have been obtained for the amplitude and for the acceleration of a large number of earthquakes.

Figure A15.2 gives a seismogram showing the arrival of the P, S and L waves.

There are a number of seismographic networks. A region of high seismic activity may have a number of such networks. Thus, in California, Berlin describes networks operated by the US Geological Survey, the Nuclear Regulatory Commission, the University of California and several other bodies. At the international level there is the World-wide Standard Seismographic Network (WSSN).

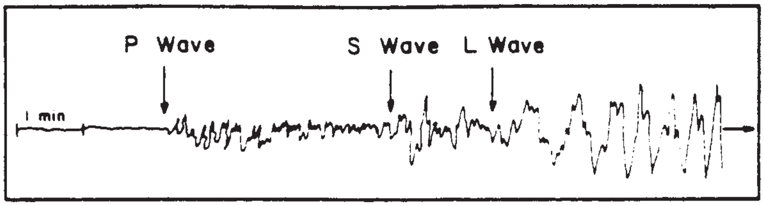

Figure A15.2 *A seismogram showing P, S and L waves (National Oceanic and Atmospheric Administration, 1972)*

A15.2 Earthquake Characterization

The quantitative characterization of earthquakes is largely in terms of magnitude and intensity scales and of empirical correlations. Earthquakes are a geographical phenomenon and hence in many cases the original correlations have been derived for a specific region, often California. This should be borne in mind in respect of the relationships quoted below.

A15.2.1 Focus and epicentre

For a particular location the distance r to the epicentre is the epicentral distance and the distance to the focus is the focal distance so that

$$R^2 = h^2 + r^2 \qquad \text{[A15.2.1]}$$

where R is the focal distance, or slant distance (km), h the distance between the focus and the epicentre, or focal depth (km) and r the epicentral distance (km). Use is often made of a modified focal distance defined as

$$R^2 = h^2 + r^2 + k^2 \qquad \text{[A15.2.2]}$$

where k is a modifying factor (km). Esteva (1967) has given an estimate of $k = 20$.

A15.2.2 Magnitude and magnitude scales

The severity of an earthquake is defined in terms of its magnitude and intensity. The more objective is the magnitude, which is a measure of the total energy in the seismic waves.

A scale for the representation of the magnitude of an earthquake was devised by Richter and magnitude is commonly quoted in terms of the value on the Richter scale. The value is a measure of the ratio of the maximum amplitude recorded for the earthquake in question to the maximum amplitude for a standard earthquake, with both measurements made on a standard seismograph located at a standard distance from the earthquake, the instrument being a Wood–Anderson seismograph of defined characteristics.

The magnitude M of an earthquake may be measured locally, in which case it is denoted M_L, or at a distant point through surface waves, when it is denoted M_S. The two differ and in order to overcome this difficulty Gutenberg introduced the concept of unified magnitude m, or m_b, which depends on the body waves. The magnitudes quoted in the literature are frequently not fully defined.

The relation of Richter for the magnitude of a local earthquake is

$$M_L = \log_{10}(A/A_O) \qquad \text{[A15.2.3]}$$

where A is the maximum amplitude (mm), A_O the maximum amplitude of the standard earthquake (mm) and M_L the local magnitude, under the standard conditions described. The value of A_O assigned to the standard earthquake is $A_O = 0.001$ mm.

The Richter scale is thus a logarithmic one and an earthquake that is one unit higher on the scale has an amplitude 10 times as great as that below it.

The Richter magnitude scale is open-ended with no lower or upper limit. The scale point 0 is an arbitrary one.

A number of equations have been developed for the surface wave magnitude M_S and the body magnitude m_b, relating these quantities to the characteristics of the seismographic record.

It is often necessary to convert one type of magnitude to another. Two widely used approximate relations are those given by Richter (1958)

$$M_S = 1.59m_b - 3.97 \qquad \text{[A15.2.4]}$$

and

$$m_b = 2.5 + 0.63M_S \qquad \text{[A15.2.5]}$$

These two magnitudes agree at a value of about 6.8; below this m_b is larger and above it M_S is larger. There is also the empirical equation of Gutenberg (1956)

$$m_b = 1.7 + 0.8M_L - 0.01M_L^2 \qquad \text{[A15.2.6]}$$

A15.2.3 Energy

The relationship between the total seismic wave energy and the surface wave magnitude was the subject of a series of studies by Gutenberg and Richter, who produced between 1936 and 1956 a number of correlations. The 1956 Gutenberg–Richter equation for energy, quoted by Gutenberg (1956), is

$$\log_{10} E = 11.8 + 1.5M_S \qquad \text{[A15.2.7]}$$

where E is the total energy (erg).

Gutenberg has also given the following relations between the total energy and the other magnitudes:

$$\log_{10} E = 9.9 + 1.9M_L - 0.024M_L^2 \qquad \text{[A15.2.8]}$$

$$\log_{10} E = 5.8 + 2.4m_b \qquad \text{[A15.2.9]}$$

An earthquake that is one unit higher on the Richter magnitude scale has an energy some 27 times as great as that below it.

A15.2.4 Frequency and return period

A correlation between the frequency and magnitude of earthquakes was obtained by Gutenberg and Richter. Their equation is given by Richter (1958) as

$$\log_{10} N = a - bM \qquad \text{[A15.2.10]}$$

where N is the frequency of earthquakes exceeding that magnitude (per year), and a and b are constants. This equation is generally referred to as the Gutenberg–Richter equation for frequency.

Various workers have used the Gutenberg–Richter equation to correlate the frequency of earthquakes for different regions and periods.

Estimates for the relationship between the magnitude and the frequency of earthquakes world-wide by Gutenberg and Richter (1940) are given below together with later estimates by the National Earthquake Information Center (NEIC) (1970).

M_L	*Gutenberg and Richter description*	*Annual frequency*	*NEIC description*	*Annual frequency*
>8.0	Great earthquakes	1	Great	1.1
7.0–7.9	Major earthquakes	10	Major	18
6.0–6.9	Destructive shocks	100	Large (destructive)	120
5.0–5.9	Damaging shocks	1,000	Moderate (damaging)	1,000
4.0–4.9	Minor strong shocks	10,000	Minor (damage slight)	6,000
3.0–3.9	Generally felt	100,000	Generally felt	49,000

A15.2.5 Intensity and intensity scales

The other main measure of the severity of an earthquake is the intensity. Intensity is a measure of the severity of an earthquake as experienced at a particular location.

Thus, an earthquake of a given magnitude may have different intensities at different locations. However, in so far as interest centres on the effects at a given location, such as a town, an intensity may be assigned for the earthquake at that location. Thus, an intensity is often quoted for an earthquake identified by town and year.

There are several scales for the representation of the intensity of an earthquake. One of the earliest was the Rossi–Forelli (RF) scale. This was modified by Mercalli to give the Mercalli scale and subsequently modified again in 1931 to give the Modified Mercalli (MM) scale. The MM scale has since undergone further revisions. The MM scale is the most widely used intensity scale. It is shown in Table A15.2

One way of characterizing a particular earthquake is by an isoseismal map showing the contours of the MM scale intensities.

The MM scale gives the intensity as a Roman numeral. For quantitative work the intensity is required as a numerical value. The practice is to use the Roman numeral directly. Thus, an earthquake of intensity between MM scale I and II has an intensity of 1.5. This is the approach described by Richter (1958, p. 140).

There are numerous empirical relationships that have been developed between intensity and other earthquake parameters. One is the equation of Gutenberg and Richter (1956) between local magnitude, intensity and epicentral intensity

$$M_L = I + I_O/3 \qquad [A15.2.11]$$

where I is the intensity and I_O the epicentral intensity.

Another is the relation of Esteva and Rosenblueth (1964) between intensity, local magnitude and focal depth

$$I = 8.16 + 1.45M_L - 2.46 \log_{10} h \qquad [A15.2.12]$$

The following relation is given by Richter (1958) between peak ground acceleration (PGA) and intensity:

$$\log_{10} a = \frac{I}{3} - \frac{1}{2} \qquad [A15.2.13]$$

where a is the PGA (cm^2/s).

A15.3 Earthquake Effects

The effects of an earthquake may be classified as direct or indirect. The direct effects include

(1) ground shaking;
(2) ground lateral displacement;
(3) ground up-lift and subsidence;

and the indirect effects

(4) ground settlement;
(5) soil liquefaction;
(6) slope failure:
    (a) avalanches, landslides,
    (b) mud slides;
(7) floods;
(8) tsunamis and seiches;
(9) fires.

Of the direct effects, ground shaking usually occurs over a wide area. At faults, fault displacement results in lateral movement of the ground and surface breaks. The distance over which the surface breaks occur is variable. There may be tectonic up-lift and subsidence.

Of the indirect effects, ground settlement may occur due to compaction of unconsolidated deposits. There may be soil liquefaction, giving a 'quick condition' failure. Slope failures may occur in the form of avalanches, landslides and mud slides.

The earthquake may cause floods due to the failure of dams or levees. In certain regions there may occur tsunamis. A tsunami is a wave occurring in relatively shallow water and is caused by vertical displacement of the earth beneath the water. Seiches may also occur. A seich is a standing wave on the surface of water such as a lake.

The destruction of buildings and the rupture of gas mains tends to give rise to widespread fires.

A15.4 Earthquake Incidents

Tabulations of earthquakes are given in a number of texts. Eiby (1980) gives a chronological list; this includes the values of the magnitudes. Berlin gives tables showing earthquakes that have caused major fatalities world-wide, major fatalities in the United States and major property damage in the United States. Bolt (1988) gives tables of earthquakes world-wide, in the United States and Canada and in Central and South America; the North American list gives MM intensities. Berlin (1980) also gives lists of earthquakes with special features such as shattered earth, vertical displacement and bad ground and soil liquefaction effects.

Table A15.3 gives some earthquakes in this century that have caused major loss of life world-wide or property damage in the United States. Table A15.4 lists some earthquakes that are frequently discussed in texts on earthquakes or earthquake-resistant design as having features

Table A15.2 *The Modified Mercalli intensity scale*

Intensity	*Description*[a]
I	Not felt. Marginal and long-period effects of large earthquakes
II	Felt by persons at rest, on upper floors, or favourably placed
III	Felt indoors. Hanging objects swing. Vibration like passing of light trucks. Duration estimated. May not be recognized as an earthquake
IV	Hanging objects swing. Vibration like passing of heavy trucks; or sensation of a jolt like a heavy ball striking the walls. Standing motor cars rock. Windows, dishes, doors rattle. Glasses clink. Crockery clashes. In the upper range of IV, wooden walls and frame creak
V	Felt outdoors; direction estimated. Sleepers wakened. Liquids disturbed, some spilled. Small unstable objects displaced or upset. Doors swing, close, open. Shutters, pictures move. Pendulum clocks stop, start, change rate
VI	Felt by all. Many frightened and run outdoors. Persons walk unsteadily. Windows, dishes, glassware broken. Knickknacks, books, etc., off shelves. Pictures off walls. Furniture moved or overturned. Weak plaster and masonry D cracked. Small bells ring (church, school). Trees, bushes shaken (visibly, or heard to rustle)
VII	Difficult to stand. Noticed by drivers of motor cars. Hanging objects quiver. Furniture broken. Damage to masonry D, including cracks. Weak chimneys broken at roof line. Fall of plaster, loose bricks, stones, tiles, cornices (also unbraced parapets and architectural ornaments – CFR). Some cracks in masonry C. Waves on ponds; water turbid with mud. Small slides and caving in along sand or gravel banks. Large bells ring. Concrete irrigation ditches damaged
VIII	Steering of motor cars affected. Damage to masonry C; partial collapse. Some damage to masonry B; none to masonry A. Fall of stucco and some masonry walls. Twisting, fall of chimneys, factory stacks, monuments, towers, elevated tanks. Frame houses moved on foundations if not bolted down; loose panel walls thrown out. Decayed piling broken off. Branches broken from trees. Changes in flow or temperature of springs and wells. Cracks in wet ground and on steep slopes
IX	General panic. Masonry D destroyed; masonry C heavily damaged, sometimes with complete collapse; masonry B seriously damaged. (General damage to foundations – CFR.) Frame structures, if not bolted, shifted off foundations. Frames cracked. Serious damage to reservoirs. Underground pipes broken. Conspicuous cracks in ground. In alluviated areas sand and mud ejected, earthquake fountains, sand craters
X	Most masonry and frame structures destroyed with their foundations. Some well-built wooden structures and bridges destroyed. Serious damage to dams, dikes, embankments. Large landslides. Water thrown on banks of canals, rivers, lakes, etc. Sand and mud shifted horizontally on beaches and flat land. Rails bent slightly
XI	Rails bent greatly. Underground pipelines completely out of service
XII	Damage nearly total. Large rock masses displaced. Lines of sight and level distorted. Objects thrown into the air

[a] CFR, Charles F. Richter additions to the 1931 scale. Masonry A, good workmanship, mortar, and design; reinforced, especially laterally, and bound together by using steel, concrete, etc.; designed to resist lateral forces. Masonry B, good workmanship and mortar; reinforced, but not designed in detail to resist lateral forces. Masonry C, ordinary workmanship and mortar; no extreme weaknesses like failing to tie in at corners, but neither reinforced nor designed against horizontal forces. Masonry D, weak materials, such as adobe; poor mortar; low standards of workmanship; weak horizontally.

From *Elementary Seismology* by Charles F. Richter, W. H. Freeman and Company, Copyright © 1958. Reproduced by permission.

of particular interest; accounts of these earthquakes are given in the references shown in the table.

Table A15.3 gives only earthquakes that have occurred since 1920. It nevertheless includes some that have caused very large loss of life, in particular those at Kwanto in Japan in 1923 and Tangshan in China in 1976, where the death tolls were 143,000 and 250,000, respectively.

The San Francisco earthquake in 1906 was one of large magnitude (8.3) and high intensity (XI). The ground shook for some 40–60 s. Notable features were the difference in damage between buildings on good ground and those on bad ground and the outbreak of large numbers of fires. Some 700 people were killed.

The Tokyo–Yokohama earthquake in Japan in 1923, also known as the Kwanto earthquake after the province most affected, was another with large magnitude (8.3). Tokyo and Yokohama, both very densely populated, were almost completely destroyed. Fire broke out on a large scale and it was this rather than building collapse that was responsible for the high death toll of some 143,000.

These two disasters gave impetus to the development of seismological studies and seismic engineering in the United States and Japan.

The earthquake in Imperial Valley, California, in 1940, also known as El Centre, which had a magnitude of 6.9, is of particular interest to seismologists. A seismograph in El Centre recorded a PGA of some one third that of gravity. For many years this was the only record available to engineers showing clearly the ground shaking caused by a large earthquake close to its source.

Another earthquake that has been of particular interest to seismological engineers is that at Parkfield in 1966 with a magnitude of 5.6. The Parkfield earthquake was less destructive than that at El Centre in 1940, but it gave a PGA of 0.5 g compared with that of 0.33 g for El Centre.

The interest in these two earthquakes has been enhanced by a further earthquake at Imperial Valley in 1979, which was of similar size to the 1940 event, and by the fact that Parkfield has been the subject of one of the principal examples of the prediction of future earthquakes.

Table A15.3 Some earthquakes causing major loss of life or property damage

A Earthquakes causing major loss of life[a]

Year	*Location*	*Number of deaths*
1920	Kansu, China	180,000
1923	Tokyo-Yokohama, Japan	143,000
1932	Kansu, China	70,000
1935	Quetta, India	60,000
1939	Chilian, Chile	30,000
1939	Erzincan, Turkey	23,000
1960	Agadir, Morocco	14,000
1962	North-western Iran	14,000
1968	North-eastern Iran	11,600
1970	Peru	66,000
1972	Managua, Nicaragua	12,000[b]
1976	Guatemala	22,000
1976	Tangshan, China	≈ 250,000[c]
1976	Hopei, China	655,000

B Earthquakes causing major property damage in the United States[d]

		Property damage ($ million)
1906	San Francisco, CA	24 500 (fire loss)
1933	Long Beach, CA	40
1952	Kern County, CA	60
1964	Alaska and US West Coast	500
1971	San Fernando, CA	553

[a] Earthquakes since 1920 causing 10,000 or more deaths.

[b] This is Berlin's figure; Bolt gives 5000.

[c] For China in 1976 this is Bolt's entry; Berlin gives Hopei with 655,000 deaths.

[d] Earthquakes since 1900 causing $40 million or more property damage.

Sources: Berlin (1980); Bolt (1985).

In 1954 the oil fields of Kern County, California, were subject to an earthquake. The damage caused by this event to process installations is described in Section A15.5.

Several earthquakes have occurred in areas that were not regarded as major seismic risk zones. One of these occurred at Agadir in 1960. The epicentre of the earthquake was close to the town and although of relatively low magnitude (5.8) it was very destructive. Much of the town consisted of old buildings and this was a further major contributor to the destruction. The death toll is quoted as 14,000.

The earthquake at Skopje in 1963 had similar features. The area was not regarded as one of particular seismic activity. Its epicentre was close and it was highly destructive despite being of relatively low magnitude (6.0). About 1200 people were killed.

Both the Agadir and Skopje earthquakes were practically a single shock.

The earthquake at Mexico City in 1957, which had a magnitude of 7.5, was notable for the damage to buildings standing on bad ground. In locations where the soil was alluvium, there was widespread soil liquefaction. The old lake bed area of the city experienced intensities of VII, whereas at other locations the intensities were V or less.

Another earthquake in which there was extensive damage due to soil liquefaction was that at Niigata in 1964, which had a magnitude of 7.5. The Niigata earthquake gave impetus to the study of soil effects, and particularly soil liquefaction.

A large earthquake, of magnitude 8.4, occurred in Alaska in 1964. This event was notable for its long duration and wide reach, and for its destructiveness. The earth shook for about 3 min. Ground fissures occurred 725 km from the epicentre. Quite large areas suffered up-lift or subsidence. The docks at the port of Anchorage suffered large displacements. The damage caused to process installations by this event is described in Section A15.5.

The San Fernando earthquake of 1971 has several features of interest. It is a prime instance of the shattered earth effect described in Section A15.7. In localized areas the intensity was assessed as high as XII. Ground accelerations were the highest recorded at 1.25 and 0.7 g for horizontal and vertical accelerations, respectively. Some of the damage effects, particularly to lifelines, are described in Section A15.5.

As far as concerns the United Kingdom, mention should be made of the Great British Earthquake of April 22, 1884, near Colchester, to which a magnitude of 5.3 has been assigned. The PGA has been estimated as between 0.07 and 0.2 g.

A15.5 Earthquake Damage

There are available numerous accounts of earthquake damage. Most texts on seismology contain descriptions and illustrations of the damage caused by particular earthquakes. These accounts deal largely, often exclusively, with damage to buildings, which is not the prime concern here. There is rather less information available on damage to plant.

A review of seismic damage to process plant and utilities has been given by Alderson (1982 SRD R246). Information is also given by Berlin (1980).

The earthquake in Kern County near Bakersfleld in 1952 (Case History A20) occurred in an oil production area. The production rate of several oilfields was affected. Many storage tanks skidded but only a few collapsed.

The most spectacular effect occurred at the Paloma Cycling Plant, where the earthquake caused two of the five large butane spheres to collapse, rupturing pipework and giving a major release. A large vapour cloud formed and was ignited at electrical transformers almost three blocks away. There was a large vapour cloud explosion, followed by a major fire.

On vessels, columns and tall heat exchangers steel foundation bolts were stretched. The top of one vessel standing 60 ft high and weighing some 100 te was estimated from the 1 in. stretch of the bolts at its base to have moved over an arc of 3 ft. There were no major failures, however, of horizontal vessels or pressure storage tanks. High pressure pipework withstood the earthquake well, although there were thermal failures in the subsequent fire; only one cold failure was reported.

At other installations damage was minimal. At one plant oil sloshing in storage tanks broke through the roof. At one pipeline station pipe displacements of 5 in. were found. Elevated water tanks with no lateral support suffered badly. Of the 12 in the area, two collapsed and seven had suffered damage to their supports.

Table A15.4 *Some earthquakes of particular interest*

Date		*Magnitude*	*Reference*
18 April 1906	San Francisco, CA	8.3	
1 Sept. 1923	Kwanto, Japan	8.3	
18 May 1940	Imperial Valley (El Centre)	6.9	Dowrick (1977)
21 July 1952	Kern County, CA	7.7	Berlin (1980); Alderson (1982)[a]
21 Dec. 1954	Eureka, CA	6.6	Alderson (1982)
22 March 1957	San Francisco, CA	5.3	Alderson (1982)
28 July 1957	Mexico City	7.5	Berlin (1980)
29 Feb. 1960	Agadir, Morocco	5.8	Eiby (1980)
22 May 1960	Arauco, Chile	8.4	Eiby (1980)
26 July 1963	Skopje	6.0	Alderson (1982)
27 March 1964	Alaska	8.4	Berlin (1980); Alderson (1982)
16 June 1964	Niigata, Japan	7.5	Dowrick (1977); Berlin (1980);
27 June 1966	Parkfleld	5.6	Dowrick (1977); V.W. Lee and Trifunac (1987); Bolt (1988)
19 Aug. 1966	Varto, Turkey	7	Berlin (1980)
9 Feb. 1967	Columbia	6.7	Alderson (1982)
31 May 1970	Chimbote, Peru	7.7	Eiby (1980)
9 Feb. 1971	San Fernando, CA	6.8	Berlin (1980)
4 Feb. 1975	Liaoning Province	7.4	Bolt (1988)
6 Sept. 1975	Lice, Turkey	6.7	Berlin (1980)
6 May 1976	Friuli, Italy	6.5	Alderson (1982)
27 July 1976	Tangshan	8.0	Bolt (1988)
13 Aug. 1978	Santa Barbara, CA	5.8	Alderson (1982)
15 Oct. 1979	Imperial Valley (El Centre)	–[b]	Bolt (1988)
2 May 1983	Coalinga, CA	6.7 (M_L)	Bolt (1988)
3 March 1985	Algarrobo, Chile	7.8	Bolt (1988)
19 Sept. 1985	Ixtapa, Mexico	8.1	Bolt (1988)

[a] Alderson (1982) = Alderson (1982 SDR R246).

[b] This earthquake is described by Bolt (1988) as 'similar' to that in Imperial Valley in 1940.

There was damage to a number of electrical power plants and electrical distribution systems.

Overall plant management in this area were earthquake-conscious. Generally, tall vessels were well anchored and pipework provided with flexibility.

Another instructive case is the earthquake at San Fernando in 1971. This was the first occasion on which a major effort was made to investigate the effects on lifeline systems.

The earthquake was particularly severe over an area of some 30 km^2 at San Fernando and Sylmar. Violent ground movement in this area broke gas mains and valves, but this was the only area where the gas distribution system suffered serious damage. The water supply system to San Fernando was devastated.

The earthquake disrupted power supplies to large parts of Los Angeles. There was damage to Sylmar Converter Station (40% equipment loss), Olive Switching Station (80% loss) and Sylmar Switching Station (90% loss). The restoration time for the first of these was estimated at 1.5–2 years.

At the Sylmar Central Office of the local telephone company 91 te of automatic switching equipment were destroyed, putting the telephone service out of action.

The transport system was also severely affected. Some 62 bridges were damaged, of which 25% collapsed or were severely damaged.

Other earthquakes for which Alderson gives some information on damage to plant include Eureka in 1954, San Francisco in 1957, Alaska in 1964 and Santa Barbara in 1978. It is not uncommon for there to be some rupture of water mains, often due to a combination of corrosion and pressure surge. Some rupture of gas pipes also occurs.

In the 1964 Alaska earthquake there were many failures of tanks and pipework. Tanks of all kinds moved and, if not well anchored, toppled over. Pipes failed at screwed joints and poorly guided thermal loops, as did long unsupported cast iron pipe runs.

A15.6 Ground Motion Characterization

The ground motion caused by an earthquake may be characterized in terms of the peak values of the acceleration, velocity and displacement; of the full time-domain responses of these quantities, particularly the accelerogram, or of the response spectrum. The latter is described below.

The information required for design depends on the method used. Some methods utilize the peak acceleration. The trend is, however, to use the full response in the form of an accelerogram or a response spectrum.

For a single parameter, such as the PGA, methods of prediction are available. For a full response, such as an accelerogram or response spectrum, it is necessary to select one that is judged appropriate for the site.

A15.6.1 Strong ground motion

The typical pattern of ground motion is a sudden transition from zero to maximum shaking, followed first by a period of more or less uniformly intense vibration and then by a rather gradual attenuation of this vibration.

There are, however, appreciable differences in the ground motion from different earthquakes. Newmark and Rosenblueth (1971) distinguish four types of strong ground motion: (1) practically a single shock; (2) a moderately long, extremely irregular motion; (3) a long ground motion exhibiting pronounced prevailing periods of vibration; and (4) a ground motion involving large-scale, permanent deformations of the ground.

They give the earthquakes at Agadir in 1960 and Skopje in 1963 in the first category; that at El Centre in 1940 in the second; that at Mexico City in 1964 in the third and those in Alaska and at Niigata, both in 1964, in the fourth.

A15.6.2 Peak ground motion

Methods are available for the estimation of the peak ground motion parameters. For ground acceleration one widely quoted relation is that given by Donovan (1973), derived from data for several seismic regions:

$$a = \frac{1080\ \exp(0.5M)}{(R + 25)^{1.32}} \qquad [A15.6.1]$$

where a is the PGA (cm/s^2).

Esteva (1974) has used data for earthquakes in California to obtain equations for both PGA and peak ground velocity:

$$a = \frac{5600\ \exp(0.8M)}{(R + 40)^2}, \quad R>15 \qquad [A15.6.2]$$

$$v = \frac{32\ \exp M}{(R + 25)^{1.7}}, \quad R>15 \qquad [A15.6.3]$$

where v is peak ground velocity (cm/s).

For peak ground displacement Newmark and Rosenblueth (1971) give the following approximate empirical relation

$$5 \le \frac{ad}{v^2} \le 15 \qquad [A15.6.4]$$

where d is peak ground displacement (cm). The lower limit of 5 and the upper limit of 15 apply to large epicentral distances, say 100 km, and to small ones, respectively.

A15.6.3 Vibration parameters

The vibration characteristics of the earthquake are also important. Correlations are available for the fundamental frequency, or period, of earthquakes. These are described by Dowrick (1977).

A15.6.4 Accelerograms

The basic seismographic measurement is the accelerogram. Profiles of velocity and displacement may be obtained from this by integration. A set of such profiles is illustrated in Figure A15.3.

There are now available accelerograms for quite a large number of real earthquakes. Collections are maintained by major seismographic institutions such as the California Institute of Technology.

Accelerograms are also available for simulated earthquakes. A set of eight such accelerograms have been

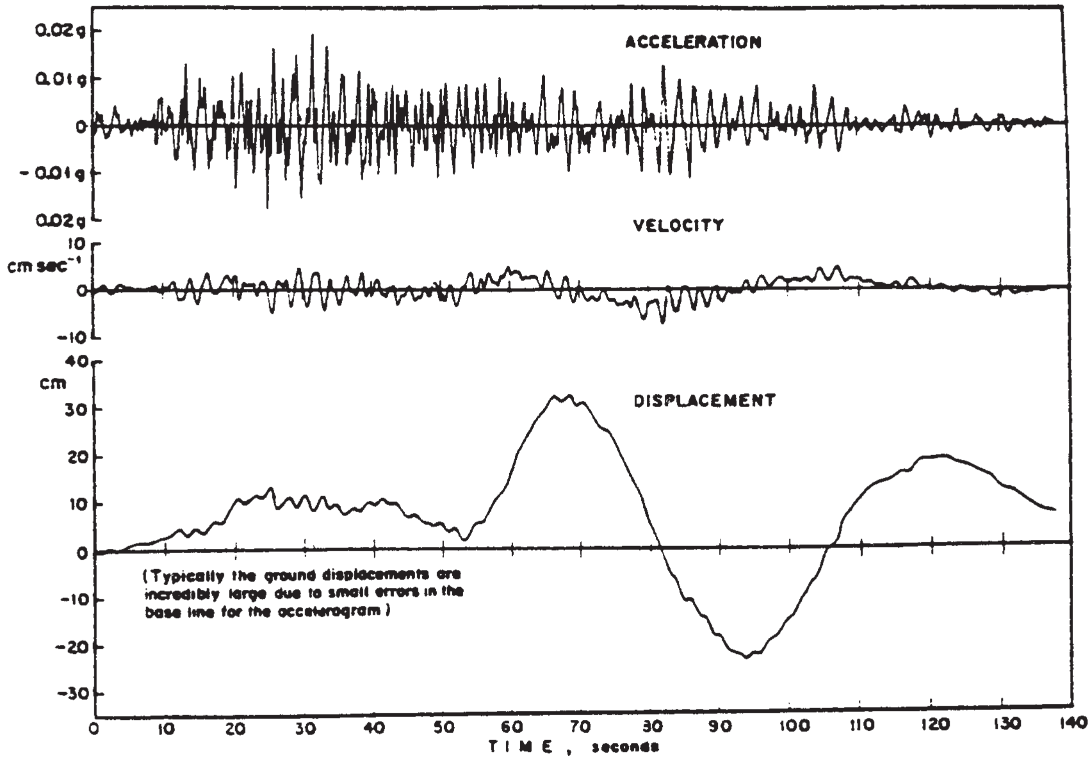

Figure A15.3 *Time histories of acceleration, velocity and displacement of the earthquake at Mexico City, 6 July 1964 (after Rosenblueth, 1996)* described by Jennings, Housner and Tsai (1968). There exist computer codes for the generation of simulated earthquakes.

The design of earthquake-resistant structures is increasingly based on dynamic analysis. The structure is modelled using the appropriate equations of motion and this model is then perturbed by a suitable forcing function. The natural forcing function to use is an accelerogram.

A15.6.5 Response spectra

The main interest in design, however, is in the maximum values of certain responses of the structure. Many of these depend only on the natural period and the degree of damping. A plot which shows the response of one of the parameters acceleration, velocity or displacement for a given degree of damping is known as a response spectrum and that for a set of values of the damping as the response spectra.

Response spectra may be obtained from accelerograms by Fourier analysis and there are computer codes to do this.

There are response spectra available for both real and simulated earthquakes. A regulatory body may specify a standard set of response spectra for use in design.

Figure A15.4 shows a set of response spectra issued by the NRC.

A15.7 Ground, Soils and Foundations

The characteristics of the ground have profound effects on virtually all aspects of earthquake assessment and earthquake-resistant design.

A15.7.1 Ground effects

Experience of earthquakes shows that differences in the ground can result in large differences in the damage done. According to Eiby (1980), in extreme cases this can amount to up to four degrees of intensity on the MM scale. It is therefore important to avoid siting structures on bad ground.

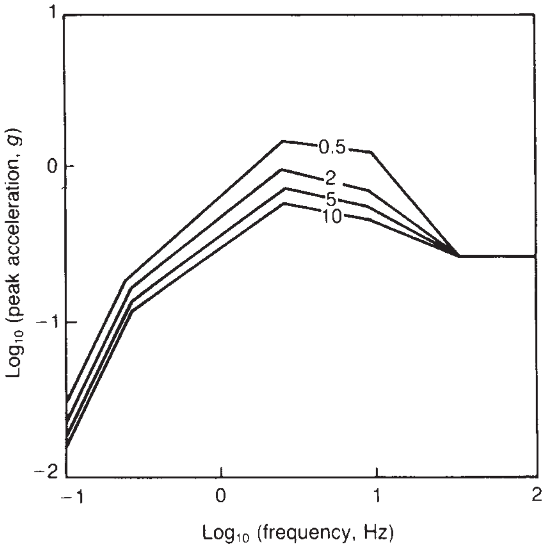

Figure A15.4 *Seismic design response spectra given in Regulatory Guide 1.60 of the Nuclear Regulatory Commission (Nuclear Regulatory Commission, 1973). The four damping levels shown are for viscous damping of 0, 5, 2, 5 and 10% of critical damping)*

Bedrock is generally regarded as a sound foundation and alluvium as less satisfactory. Alluvium tends to absorb the effects of small earthquakes but to amplify those of large ones, giving rise to the effect of soil amplification.

A particular effect of bad ground is soil liquefaction, which can result in very severe damage. This is considered below.

An important class of locations where alluvium is present is old river terraces, which are often the site of ports.

As just stated, structures on the same site may suffer quite different degrees of damage due to differences in the quality of the ground. In the earthquake in 1957 in Mexico MM intensities of VII were determined for the old lake bed area of Mexico City, while other parts had intensities of V or less. The earthquake at Varto, Turkey, in 1966 destroyed some buildings in a school complex but not others, the large difference in damage being attributed to the effect of very localized differences in the ground

Where a structure straddles two types of soil, damage tends to be enhanced, and this is to be avoided.

It is not universally the case that ground motion is worse in bad ground than in bedrock. Where the rock is on a ridge there can occur a phenomenon variously known as shattered earth, exploded outcrop or churned ground. The 1971 San Fernando earthquake produced numerous instances.

The susceptibility of steep slopes to avalanches is affected by the nature of the soil. A major slope failure occurred in the earthquake at Chimbote in Northern Peru in 1970 when an avalanche with an estimated velocity of 200–400 km/h travelled 18 km, buried whole towns and killed some 20,000. However, slope failures can also occur on relatively gentle slopes. In the Alaska earthquake in 1964 slope failures occurred due to liquefaction of lenses of sand contained in clay deposits.

A15.7.2 Soil settlement and liquefaction

Some of the worst earthquake damage has been due to a quick condition failure in which liquefaction of the soil has occurred. It is important, therefore, to be able to assess susceptibility to soil liquefaction. Damage may also occur due to soil compaction and settlement short of liquefaction.

The behaviour of a soil under earthquake loading is a function of the strain magnitude, strain rate and number of cycles of loading. Some soils increase in strength under rapid cyclic loading, while others, such as saturated sands, tend to lose strength.

Broadly, gravel and clay soils are not susceptible to liquefaction and dense sands are less likely to liquefy than loose ones.

Two important characteristics of a soil bearing on liquefaction are its cohesion and its water content. Saturated cohesionless soils are prone to liquefaction. A full discussion of the effect of cohesion and saturation on soil liquefaction is given by Newmark and Rosenblueth (1971).

The susceptibility of a cohesionless soil to liquefaction depends on its water content. For a dry cohesionless soil grain size is another important factor. For a medium grain size soil experiencing vibration a critical void ratio exists below which it tends to dilate and above which it tends to reduce in volume. This effect has been modelled by Barkan (1962). Other effects which can occur are breakage in large grain soils and air entrapment and soil liquefaction in fine grain soils.

A saturated cohesionless soil is most prone to liquefaction. The effect is not well understood, although it is known that relative density, confining pressure and drainage conditions are three important variables. Loose sands often liquefy after only a few loading cycles, whereas dense ones may require several hundred cycles. Conditions which prevent water from escaping promote liquefaction.

Extensive soil liquefaction occurred in the earthquake at Niigata in 1964. There was loose sand and water was not able to escape, partly due to the extent of the foundations.

With a saturated cohesive soil the strength tends to increase due to strain rate but to decrease due to cyclic loading. The net effect may be to increase or decrease the strength, depending on the nature of the soil. In a very sensitive soil a decrease in strength may set in after only a few cycles, whereas with a relatively insensitive one the strength may still be increasing after some 50 cycles.

A15.7.3 Site investigation

It is practice to carry out a site investigation to determine the characteristics of the ground. An account of the laboratory and field tests and of the information which they yield is given by Dowrick (1977). Laboratory tests on relative density and particle size distribution and field tests on groundwater conditions and penetration resistance bear on the problems of soil liquefaction and settlement, while field tests on soil distribution, layer depth and depth to bedrock, groundwater conditions and the natural period of the soil provide data for response calculations. Other tests may be performed to obtain the shear modulus and damping characteristics.

In addition to the use of drill holes to make the field tests just described, use may also be made of other techniques such as inducing and measuring vibrations.

A15.7.4 Design basis earthquake

Where dynamic analysis is to be performed, it may be necessary to modify the accelerogram to take account of the nature of the ground. The case of bedrock would seem at first sight to be the most straightforward, but this is not necessarily so, since most accelerograms are for softer soils, and there are very few for bedrock. The modification of accelerograms to take account of ground conditions is a specialist matter. An account is given by Dowrick (1977).

The ground motion is also affected by any structure placed on it. The accelerogram relevant to the site as a whole is therefore the free field accelerogram.

A15.7.5 Soil–structure interaction

It has been found by experience that there is an appreciable interaction between the soil and the structure and that it is necessary to take this into account.

The effects of bad ground have already been described. One such effect is soil amplification of the earthquake vibrations.

The effects of soil–structure interaction (SSI) are to modify the dynamics of the structure and to dissipate its vibrational energy.

In general, damage is greater if the natural period of a structure is similar to that of the soil on which it is built, for example a low, short-period building on a short-period soil deposit or a tall, long-period building on a long-period deposit. In the earthquake in 1957 at Mexico City extensive damage was done to long-period structures standing on deep (>100 m) alluvium. Another case where the natural period of structures suffering damage appeared closely correlated with the depth of subsoil was in the earthquake at Caracas, Venezuela, in 1967.

The Uniform Building Code (UBC) in the United States, described below, originally contained a soil amplification factor that was then removed due to lack of knowledge as to what the factor should be. The 1976 version contains a site–structure resonance factor S. This factor is a function of the ratio T/T_s where T and T_s are the natural periods of the structure and soil, respectively.

A soil deposit may be characterized by the width and depth of soil overlying the bedrock. The natural period increases with the depth of the deposit. Relations are available for the determination of the natural period of horizontal vibration of a soil deposit. Dowrick (1977) gives the equation

$$T = 4H/v_s \qquad [A15.7.1]$$

where H is the depth of the soil layer (m), T the natural period of the soil layer (s) and v_s the velocity of the shear wave (m/s).

In determining soil–structure interaction use is made of soil–structure models. In the simpler models the soil layer is represented using models of the lumped mass with spring and damping forces type not dissimilar to those used for the structure itself.

A full dynamic analysis of soil–structure interaction is perhaps the most difficult task in earthquake engineering.

A15.8 Earthquake-resistant Design

The design of an earthquake-resistant structure includes the following principal steps:

(1) seismic assessment;
(2) ground assessment;
(3) selection of structural form;
(4) selection of the materials;
(5) overall design of the structure.

The first and second of these are considered in Sections A15.11 and A15.7, respectively.

A15.8.1 Structural form

It has been found by experience that certain structural forms resist earthquakes well while others do not. An account of the features of structural form that give earthquake resistance is given by Dowrick (1977). In broad terms the structure should be simple and symmetrical and not excessively elongated in plan or elevation. It should have a uniform and continuous distribution of strength. It should be designed so that horizontal members fail before vertical members.

The desirable degree of stiffness has been a matter of debate. The point is discussed by Dowrick, who states that either a stiff or a flexible structure can be made to work.

A15.8.2 Materials

The properties of materials of construction that confer good resistance to earthquakes include homogeneity, ductility and high strength/weight ratio.

Materials generally quoted as being suitable for earthquake-resistant structures include steel, *in situ* reinforced concrete and prestressed concrete.

A15.8.3 Static analysis

The traditional method of earthquake-resistant design is static force analysis, also referred to as the static, or equivalent static, design method.

The static method is based on the following relation for the effective horizontal force, or base shear, on the structure:

$$V = ma \qquad [A15.8.1]$$

where a is the acceleration (m/s^2), m mass (kg) and V horizontal force (N).

The value of the acceleration a used in static design is typically in the range 0.05–0.20 g.

Methods for the design of structures to withstand a horizontal force in the form of a wind load are well established in civil engineering, and the approach required for the static method for earthquake resistance is not dissimilar.

Equation A15.8.1 is the basic relation traditionally used in earthquake design codes. These codes are described in Section A15.9.

A15.8.4 Dynamic analysis

It has long been recognized that the static design method is oversimplified, and a variety of dynamic design methods have been developed.

In dynamic analysis an unsteady-state model of the structure is produced and the forcing function of the design earthquake is defined. The model is then excited using this forcing function. Methods of dynamic analysis differ in the type of model used, the use of model decomposition and the domain (time, frequency) in which the forcing is applied.

The forces estimated using the more rigorous methods of dynamic analysis can be an order of magnitude greater than those obtained from the static method.

An account of dynamic analysis is given in Section A15.10.

A15.8.5 Detailed structural design

The design methods described give information on the forces to be expected at different points in the structure. The detailed design of the various elements of the structure can then be performed.

Discussions of the behaviour of structural elements and of detailed design using different materials are given by Newmark and Rosenblueth (1971) and Dowrick (1977).

A15.8.6 Detailed non-structural design

It is also necessary to design the non-structural features for seismic resistance. Much of the damage done by earthquakes is non-structural.

These features include in-fill panels and partitions; cladding and doors and windows. An account of their design is given by Dowrick (1977).

A15.8.7 Services

The seismic resistance of services is also relevant. Guidance on this aspect is given by Dowrick (1977).

For services, the specification of the seismic resistance required is of particular importance. There may be some key services whose survival in full working order is regarded as vital.

For such essential services Dowrick suggests the use of earthquake accelerations higher than those utilized in building design; the use of dynamic rather than static design methods and of the response spectrum technique and the design for elastic rather than plastic deformation. He states that a high degree of seismic resistance can usually be obtained at relatively little extra cost.

Some services which he considers are electrical equipment, such as transformers mechanical equipment, such as boilers and pipework.

A15.8.8 Specific structures

The bulk of guidance on earthquake-resistant design relates to buildings and similar structures, but some is available for other types of structure. The types of structure relevant to process plant include columns, storage tanks and pipes.

Newmark and Rosenblueth (1971) discuss the seismic design of towers, stacks and stack-like structures; tanks and hydraulic structures and pipes. Columns are also considered by Dowrick (1977).

Accounts of particular earthquakes frequently give information on the extent of survival of, or damage to, process plant items.

A15.9 Earthquake Design Codes

Guidance on the design of earthquake-resistant structures is available in earthquake design codes. These codes have been developed particularly in the United States and Japan, and many countries have adopted or adapted the US codes.

Some earthquake design codes which have been developed in the United States include the Uniform Building Code (UBC) of the International Conference of Building Officials (ICBO); the Basic Building Code of the Building Official and Code Administration (BOCA); the Standard Building Code (SBC) of the Southern Building Code Congress International; the recommendations of the Structural Engineers Association of California (SEAOC) and the ANSI code.

The UBC appears the most widely quoted and influential. An account of the development of the code is given by Berlin (1980).

The method of design used in the code is the equivalent static method, also known as the seismic coefficient method. The account given here is based on the 1976 version of the code.

In its simplest form the basic equation of the code is

$$V = CW \qquad [A15.9.1]$$

where V is the lateral or shear force (N), W the load (N) and C a coefficient. The lateral shear force V is commonly known as the base shear coefficient.

The working equation of the code has passed through various versions. That given in the 1976 code is

$$V = ZIKCSW \qquad [A15.9.2]$$

where C is the flexibility factor; I the occupancy importance factor K the framing factor; S the site factor and Z the seismic risk zone factor.

The values to be used for the various factors are treated in the code. A discussion of these factors is given by Berlin (1980).

The flexibility factor C is a function of the natural period of the structure. There are a number of equations for the estimation of C. One principal equation is

$$C = 1/15T^{1/2} \qquad [A15.9.3]$$

where T is the fundamental period of vibration of the structure in the direction under consideration(s).

The occupancy importance factor I is 1.5 for essential facilities, 1.25 for a building where the primary occupancy is more than 300 people and 1.0 for other buildings.

The framing factor K allows for the types of structure. It has values ranging from 0.67 to 1.33. The lower value is for a structure with ductile, moment resisting frame and the higher for a structure with a box system, in which lateral forces are resisted by shear walls or braced frames. A tabulation of values is given for different types of structure.

For the seismic zone risk factor Z the United States is divided into five zones, which are defined in the code and may be characterized as follows:

Zone 0	No damage
Zone 1	Minor damage (MM intensity V and VI)
Zone 2	Moderate damage (intensity VII)
Zone 3	Major damage (intensity VIII)
Zone 4	Areas within Zone 3 close to certain major fault systems.

The values of Z for use in these zones are 3/16, 3/8, 3/4 and 1 for Zones 1, 2, 3 and 4, respectively.

An account of codes in various countries is given by Alderson (1982 SRD R246).

A15.10 Dynamic Analysis of Structures

There are a variety of methods of dynamic analysis. Features of these methods are the unsteady-state model of the structure, the use of decomposition techniques, the forcing function and the domain in which the analysis is conducted.

In the following account, dynamic analysis is described mainly in terms of a single design earthquake. It is generally recommended that the analysis be repeated for further earthquakes.

A15.10.1 Unsteady-state models of structures

Unsteady-state models of the structure are distinguished by the number of degrees of freedom (DoF). Both single degree-of-freedom (SDF) and multiple degree-of-freedom (MDF) models are used. Basic SDF and MDF models are described by Dowrick (1977).

The basic SDF model is the standard second-order system. This may be written as

$$F_{\mathrm{I}} + F_{\mathrm{D}} + F_{\mathrm{S}} = F(t) \qquad \text{[A15.10.1]}$$

where F is the applied force, or forcing function (N), F_{D} the damping force (N), F_{I} the inertia force (N) and F_{S} the elastic force (N).

Substituting for the various force terms, Equation A15.10.1 may be written as

$$m\ddot{x} + c\dot{x} + kx = F(t) \qquad \text{[A15.10.2]}$$

where c is the damping coefficient (kg/s), k the resistance (kg/s^2), m the mass of the system (kg), t the time (s) and x the displacement (m). In standard form the equation becomes

$$\frac{1}{\omega_{\mathrm{n}}^2}\ddot{x} + \frac{2\zeta}{\omega_{\mathrm{n}}}\dot{x} + x = \frac{1}{k}F(t) \qquad \text{[A15.10.3]}$$

with

$$\zeta = (c^2/4mk)^{1/2} \qquad \text{[A15.10.4]}$$

$$\omega_{\mathrm{n}} = (k/m)^{1/2} \qquad \text{[A15.10.5]}$$

where ζ is the damping factor and ω_{n} the natural frequency (s^{-1}). The damped frequency is

$$\omega = \omega n(1 - \zeta^2)^{1/2} \qquad \text{[A15.10.6]}$$

where ω is the frequency of damped oscillation (s^{-1}).

The SDF model is a lumped mass model. The distribution of mass may be taken into account by the use of an MDF model. Thus an n-storey structure might be represented by an MDF model in which the mass of each storey is assumed to be located at the floor of that storey. The model obtained then consists of a set of n equations similar to Equation A15.10.2.

In the simpler case, the model is formulated as a linear one. For some systems a linear model represents an unacceptable oversimplification and a non-linear model is required.

A15.10.2 Time-domain solution

The dynamic model is then subjected to the forcing function of the design basis earthquake. In time-domain analysis, the unsteady-state model is excited by the time forcing function, which is the accelerogram. The equations are integrated numerically and the time response of the structure is obtained. These responses include the forces, or stresses, on, and displacements of, the structural elements.

A15.10.3 Normal modal analysis

In some cases it is permissible to simplify the solution of an MDF model by a method known as normal modal, or simply modal, analysis. In this technique the vibrations in mutually perpendicular directions are treated as uncoupled and the responses are obtained for the separate modes and are then combined by superposition to give the overall responses. The method is applicable only to linear systems.

A15.10.4 Response spectra

Another approach is the response spectrum method. As described above, a response spectrum represents for a series of SDF systems with a given degree of damping the peak acceleration, velocity or displacement obtained when forced by the acceleration–time profile, or accelerogram, of the design earthquake. The family of curves for different degrees of damping constitutes the response spectra. The response spectra most commonly given are those for acceleration.

The determination of the response spectra from the forcing function $F(t)$ of the design earthquake is described by Dowrick. The displacement $x(t)$ is given by

$$x(t) = \int_0^t \frac{F(\tau)}{m\omega}\exp[-\zeta\omega(t-\tau)]\sin[\omega(t-\tau)]\,\mathrm{d}\tau \qquad \text{[A15.10.7]}$$

Then, taking $\omega \approx \omega_{\mathrm{n}}$, a response function is defined as

$$V(t) = \omega_{\mathrm{n}}x(t) \qquad \text{[A15.10.8]}$$

where $V(t)$ is the response function (m/s).

It is the maximum values of the responses that are of interest. The maximum value of the response function is termed the spectral velocity, or strictly the pseudo-spectral velocity:

$$S_v = V_{max} \quad [A15.10.9]$$

where S_v is the spectral velocity (m/s) and V_{max} the maximum value of the response function (m/s). Further

$$S_d = S_v/\omega_n \quad [A15.10.10]$$

$$S_a = \omega_n S_v \quad [A15.10.11]$$

where S_a is the spectral acceleration (m/s^2) and S_d the spectral displacement (m).

The application of the response spectra is as follows. The natural frequency and damping of the structure is determined. The response spectra are then used to obtain the peak acceleration. This peak acceleration is then applied to find the forces on, and displacements of, the structural elements.

The basic response spectra technique is described by Dowrick as essentially a special case of modal analysis, in that the method treats the system as a linear one and uses the principle of superposition. He also describes, however, adaptations of the method to non-linear analysis.

A15.10.5 Frequency domain solution

Alternatively, the analysis may be performed in the frequency domain. The method is described by Dowrick. The acceleration–time profile is converted by Fourier transform methods into an acceleration–frequency profile. This is then used to excite the model of the system. The response in the frequency domain is then converted back using the inverse transform to give the response–time profile.

R. Davies (1982) describes the use of a version of this approach. The acceleration–time profile of the design earthquake, the accelerogram, is converted by Fourier analysis into an acceleration–frequency profile. The analysis then proceeds in two stages. In the first stage, using a series of frequencies from the acceleration–frequency profile, the unsteady-state model is excited at each frequency by a sinusoidal force of that frequency and with an acceleration amplitude set at an arbitrary value. The outputs are the forces on, and displacements of, the structural elements as a function of frequency. In the second stage these outputs are converted back to time profiles of forces and displacements.

A15.10.6 Selection of method

The selection of a method of dynamic analysis is discussed by Dowrick (1977). The structures to be analysed range from small, simple structures to large, complex ones. Broadly, more complex structures demand more sophisticated methods. He gives in ascending order of complexity the methods of static analysis, response spectra, modal analysis and non-linear modelling.

A15.11 Seismicity Assessment and Earthquake Prediction

The assessment of the seismic hazard to which an installation may be exposed is normally based on information about the seismicity of the area in question. In principle, this may be complemented by information from the monitoring of ground motions and prediction of any impending earthquake. However, such prediction is not sufficiently precise to be of much use for this purpose.

A15.11.1 Seismic data and maps

There are available a number of compilations of seismic maps and other information on seismicity. They include *Seismicity of the Earth and Associated Phenomena* by Gutenberg and Richter (1954); for Europe *Seismicity of the European Area* by Karnik (1968, 1971) and for Britain *A History of British Earthquakes* by Davison (1924) and *Seismicity and Seismic Hazard in Britain* by Lilwall (1976).

A15.11.2 Seismicity assessment

Seismic design or assessment normally takes as its starting point information on the relationship between the magnitude and frequency of earthquakes at the location of interest. In default of more specific information, use is generally made of the historical record.

The normal method is to use a relation such as the Gutenberg–Richter equation, Equation A15.2.10, from which the frequency of earthquakes of various magnitudes may be determined. Several return periods and magnitudes are selected for study.

For an earthquake of a particular magnitude and frequency the probability of occurrence may be estimated making some assumption about the probability distribution. A common assumption is that the incidence is random.

Then, using a relation such as that of Donovan or Esteva, Equations A15.6.1 or A15.6.2, respectively, the PGA can be obtained.

The approach taken is therefore statistical rather than geological. The potential benefits of a more geological approach are discussed by V. W. Lee and Trifunac (1987). They argue that estimates for the occurrence rates of earthquakes are over a time interval of some 10^3–10^6 years for those based on geological structure, or ‘geological seismicity’, while those based on ‘historical seismicity’ are for intervals of the order of 10^2–10^3 years.

The assessment of seismicity in Britain described below serves to illustrate the approach generally taken.

A15.11.3 Probability distributions

The frequency of earthquakes of different magnitudes is commonly obtained from the Gutenberg–Richter equation, as just described.

Use may also be made of the extreme value distribution of Gumbel (1958).

The occurrence of an earthquake of given size is commonly treated as a randomly occurring event for which the probability distribution is the Poisson distribution:

$$P = 1 - \exp(-\lambda) \quad [A15.11.1]$$

where for an earthquake of a specified size, P is the annual probability of exceedance and λ the expected annual number of earthquakes.

The possibility of complementing this by utilizing information obtained from monitoring seismological indicators points to the possible use of the Bayesian approach.

A discussion of appropriate distributions is given by Newmark and Rosenblueth (1971).

A15.11.4 Seismicity in Britain

A study of the seismicity of Britain which is frequently quoted is that of Lilwall (1976). Figure A15.5 is one of his plots showing intensities of earthquakes with a return period of 200 years.

Lilwall divides the country into the following zones: Great Glen, Comrie and Memstrie, South Wales and Herefordshire and the remainder. The first two are areas of a seismicity relatively high for Britain. The third may be regarded as typical of a relatively active area of the country.

For the frequency of earthquakes Lilwall recasts Equation A15.2.10 as

$$\log_{10} N = a' - b'm_b \qquad [A15.11.2]$$

where a' and b' are constants. He obtains the following values for a' and b':

Area	a'	b'	*Surface area* (km^2)
Overall	4.13	1.09	2.3×10^5
South Wales and Herefordshire	1.1	0.55	15,000
Remainder	4.0	1.15	2.3×10^5

The return periods for earthquakes of different magnitudes are then as follows:

Magnitude m_b	*Return period* (year)
4.0	1.5
4.5	6.0
5.0	20.0
5.5	70.0
6.0	260.0

The last two values are extrapolations beyond the observed range.

From analysis of the data, Lilwall proposes for Britain an upper limit of 5.72 for the body wave magnitude and gives the relation

$$P = 1 - \exp\left[-\frac{1}{5}\left(\frac{5.72 - m_b}{5.72 - 4.43}\right)^{2.22}\right] \qquad [A15.11.3]$$

where P is the annual probability of exceedance.

For the relation between M_S and m_b, he uses the equation of P.D. Marshall (1970):

$$M_S = 2.08m_b - 5.65 \qquad [A15.11.4]$$

For the intensity in Britain he derives, following Esteva and Rosenblueth (1964), the relation

$$I = 6.0 + 1.5M_s - 1.9 \ln R \qquad [A15.11.5]$$

or, using Equation [A15.11.4]

$$I = -2.5 + 3.1m_b - 1.9 \ln R \qquad [A15.11.6]$$

He uses for the estimation of R Equation A15.2.2 with $k = 20$.

Figure A15.5 *Seismicity map of Great Britain showing intensities of earthquakes with a return period of 200 years (Lilwall, 1976). Despite of shading give intensities of up to 5, 5–6, 6–7 and over 7 (courtesy of HM Stationery Office)*

A15.11.5 Earthquake prediction

There are a number of methods for the prediction of earthquakes. Such methods are applicable mainly to active regions. Accounts are given by Berlin (1980), Eiby (1980) and Bolt (1988).

One important concept is that of the seismic gap. Essentially, a seismic gap is an area that has not had an earthquake for some time and in which strain is accumulating. The argument is that due to this strain accumulation the probability of an earthquake increases with time.

The seismic gap concept has been applied to large earthquakes. Areas at the boundary of tectonic plates that have not had an earthquake for a long period are regarded as more likely to experience one than those that have had a recent event. The seismic gap approach has also been applied to lesser earthquakes.

It has been found that in some cases large, shallow-focus earthquakes tend to migrate along a fault zone.

There are a number of phenomena that are regarded as precursors of earthquakes. They range from fore-shocks, seismic wave anomalies and fault creep to behaviour of animals.

There are also available several earthquake precursor models. Three principal models are (1) the dilatancy model; (2) the fault creep model; and (3) the propagating deformation front model.

Attempts to predict earthquakes have met with mixed success. There is in China an established earthquake prediction programme. One much quoted case is that of the earthquake in Liaoning Province on 4 February 1975, which had a magnitude of 7.4. Officials decided that the evidence justified the issue of a warning that a strong earthquake was probable within 24 h, people left their houses and the earthquake in fact struck that evening. On the other hand no warning was issued for the earthquake at Tangshan in 1976, which had a magnitude of 8.0.

In an account of the prediction of earthquakes in California, Bolt (1988) stated that there was one definitive prediction. This was that a moderate earthquake was likely to occur near Parkfield, California, between 1987 and 1993. This was based on a simple linear prediction of the trend of earthquakes, which have occurred in 1901, 1922, 1934 and 1966.

A15.12 Design Basis Earthquake

In earthquake-resistant design, an installation is designed to withstand seismic events so that the frequencies at which various degrees of damage are incurred do not exceed the specified values. The choice of the design basis earthquake is governed by these frequency specifications.

The characterization of the ground motion of an earthquake has been described in Section A15.6. Essentially, there are three main approaches. These are characterization in terms of peak acceleration; of the response spectra or of the acceleration–time profile. These three methods of characterization accord with the three main methods of analysis described in Section A15.10: static analysis, response spectra and dynamic analysis.

A15.12.1 Seismic hazard curve

There are available empirical correlations between the frequency of exceedance and the magnitude of earthquakes and between their peak acceleration and magnitude, as described in Section A15.2. From these it is possible to obtain the relationship between the frequency of exceedance and peak acceleration. A plot of these two quantities is often referred to as a seismic hazard curve. A seismic hazard curve may be constructed for a region or for a particular site.

Figure A15.6 shows seismic hazard curves for the United Kingdom given by Alderson (1982 SRD R246). Curve A is based on the Gutenberg–Richter equation, Equation A15.2.10, and curve B by a method given by Hsieh, Okrent and Apostolakis (1975).

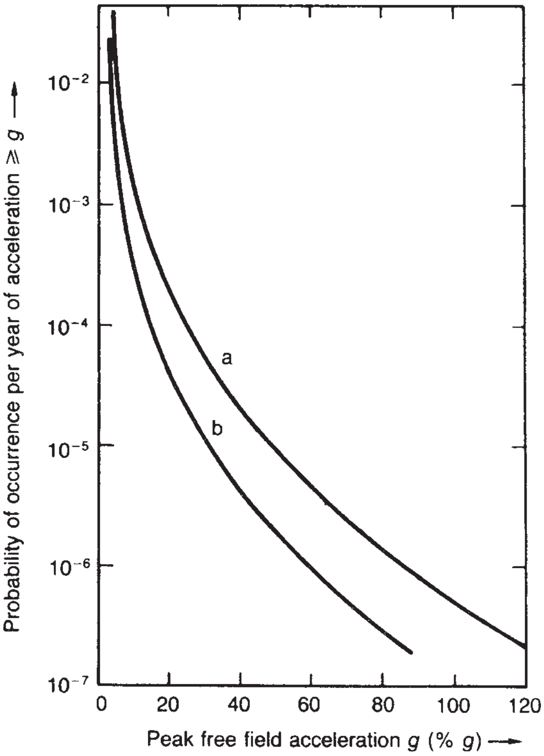

Figure A15.6 *Seismic hazard curves for the United Kingdom (Alderson, 1982 SRD R 246): (a) curve based on Gutenberg–Richter equation and (b) curve based on method of Hsieh, Okrent and Apostolakis (1975) (courtesy of the UKAEA Systems Reliability Directorate)*

A15.12.2 Response spectra

As described in Section A15.6, there are available a number of response spectra both for real earthquakes and for simulated earthquakes.

One or more of these response spectra may be selected to define the design basis earthquake. With this method also the choice is governed by the earthquake severity, and hence the return period, for which the installation is to be designed.

Two earthquakes that figure prominently in the literature are those at El Centre in 1940 and Parkfield in 1966. A number of response spectra for the El Centre earthquake and a comparison with that at Parkfield are given by Dowrick (1977). Further accounts of the Parkfield response spectra are given by D.W. Phillips (1982) and V.W. Lee and Trifunac (1987).

The seismic design response spectra given in *Regulatory Guide 1.60* of the NRC have already been mentioned and are given in Figure A15.4. They are discussed further below.

Another set of response spectra are those developed in New Zealand, as described by Dowrick (1977).

A15.12.3 Accelerograms

For accelerograms the approach is broadly similar to that for response spectra just described. One or more accelerograms may be selected with the choice governed by earthquake severity and return period.

For accelerograms also, the 1940 El Centre and 1966 Parkfield earthquakes figure prominently in the literature.

Newmark and Rosenblueth (1971) give a set of accelerograms which illustrate the distinctions which they make between different types of ground motion.

A15.13 Nuclear Installations

The seismic hazard is of particular importance for nuclear power plants and a large amount of work has been done both on seismic design and on seismic hazard assessment.

The NRC has set earthquake-resistant design criteria and has undertaken a large amount of work on seismic engineering of nuclear plants.

A15.13.1 NRC seismic design response spectra

For the purpose of nuclear plant siting, the NRC considers a fault to be active if there has been movement at least once in 35,000 years. For such a fault, it is to be assumed that the largest earthquake supported by the fault system will occur within the next 50 years.

In 1973 the NRC issued *Regulatory Guide 1.60* (*RG 1.60*) containing its seismic design response spectra, which have already been mentioned and are shown in Figure A15.4.

Background to *RG 1.60* is given by V.W. Lee and Trifunac (1987). The *RG 1.60* response spectra were developed from accelerograms of some 33 earthquakes and model the shapes of spectra that can be expected at intermediate distances from medium to large earthquakes. They state that experience of the *RG 1.60* response spectra since that date shows that they are useful for straightforward cases, but meet with difficulties for responses in the near and far fields.

These authors also describe the scaling of the *RG 1.60* response spectra for other distances, particularly for locations in the near field. The method generally used is based on scaling by the PGA, although this presents some difficulties.

Lee and Trifunac discuss approaches to the improved characterization of near-source ground motion.

A15.13.2 Seismic Safety Margins Research Program

The NRC has for some years had a major programme of work on seismic safety margins. Accounts of this work include those of Cummings (1986) and R.P. Kennedy *et al.* (1989).

In simple terms the seismic safety margin is the earthquake level at which with high confidence failure is extremely unlikely. An earthquake of this level is described as a seismic margin earthquake (SME). The SME is generally characterized by the PGA.

The main body of work is that done under the Seismic Safety Margins Research Program (SSMRP). Among the reasons for the programme were uncertainty about the size of earthquakes to be expected; a lack of experimental data to guide plant design; the potential for common mode failure due to ground shaking and the possibility that 'strengthening' might increase risk.

The SSMRP methodology involves a five-step procedure: (1) characterization of the seismic hazard; (2) determination of the response of the structure and subsystems to seismic excitation; (3) determination of the fragility functions; (4) identification of accident scenarios; and (5) calculation of the frequency of failure and release.

The seismic hazard is characterized by seismic hazard curves, response spectra and acceleration time histories based on a combination of real earthquakes, estimates from magnitude correlations, expert judgement and other methods. The necessary computations are performed by the computer code HAZARD. The soil–structure interaction and the response of structure and subsystems to seismic excitation are treated simultaneously and are handled by the SMACS code. Seismic excitation includes forcing by an ensemble of acceleration time histories in three orthogonal directions. A third code SEISIM is used to handle the radioactive release aspects.

Much of the work in the SSMRP has been concerned with the seismic fragility of items of equipment. The fragility is a function of the seismic load and is expressed as the cumulative probability of failure with load.

A15.13.3 Seismic margin estimation

A review of methods for the calculation of the seismic margin of items of equipment is given by R.P. Kennedy *et al.* (1989).

The seismic margin review of a nuclear power plant requires the determination for certain components of the High Confidence of Low Probability of Failure (HCLPF) capacity. The study describes two candidate methods for doing this, the Conservative Deterministic Failure Margin (CDFM) method and the Fragility Analysis (FA) method.

The CDFM method involves a design calculation which is essentially conventional in method but which utilizes more conservative assumptions.

In the FA method, the fragility of the equipment is modelled as a double log–normal distribution with three parameters: A_{m} the median ground acceleration and β_{R} and β_{U}, the logarithmic standard deviations representing, respectively, the randomness and the uncertainty in the median value. The two latter parameters may be subsumed in the combined parameter $\beta_{\mathrm{c}}(= (\beta_{\mathrm{R}}^2 + \beta_{\mathrm{U}}^2)^{1/2})$. The report describes the estimates made by four experts of the HCLPF by the CDFM and FA methods for a representative set of items, including a storage tank, a heat exchanger and an air tank. The bulk of the report consists of detailed calculations. The results are expressed as values of the PGA.

A15.14 Process Installations

There is rather less work published on the seismic design and seismic assessment of process plants, but there are some accounts available. Moreover, the methodologies developed in the nuclear industry are in large part applicable to the process industries.

The guide TID-7024 *Nuclear Reactors and Earthquakes* (NTIS, 1963) is quoted in the NPFA codes such as NFPA 59A: 1985 *Production, Storage and Handling of Liquefied Natural Gas* (*LNG*) for guidance on seismic loading.

A review of seismic design and assessment for process plants with special reference to major hazards is given in *Seismic Design Criteria and Their Applicability to Major Hazard Plant within the United Kingdom* by Alderson (1982 SRD R 246). Further accounts of seismic assessment of process plants include those of Ravindra (1992), and, for the United Kingdom, of R. Davies (1982), Alderson (1985) and Kunar (1983).

Methods for seismic design are given by the NRC (1979c). There is also a good deal available for particular items. For example, for liquid storage tanks accounts have been published by Veletsos and co-workers (Veletsos and Yang, 1976; Veletsos, 1984; Veletsos and Yu Tang, 1986a,b), Haroun and Housner (1981), R.P. Kennedy (1979, 1989) and Priestly *et al.* (1986). Guidance on analysis of individual failure modes is given in standard texts on structures such as Timoshenko (1936), Warburton (1976), Pilkey and Chang (1978) and, for wind loads, Sachs (1978).

A15.14.1 Seismic assessment of generic plants

R. Davies (1982) has reviewed the seismic hazard for process plants in the United Kingdom. He identifies liquefied gas storage as a matter of principal concern and describes a study to assess the risk from such storage.

The study was in three parts: the assessment of seismicity in the United Kingdom; the selection of representative containment and the identification of principal failure modes and the modelling of the seismic response of these containments.

Three levels of earthquake were defined, Levels 1–3. A Level 1 earthquake was taken as one with a return period of 150 years which would have a 0.25 probability of occurring over a plant life of 40 years. The work of Lilwall suggests that this return period corresponds to an earthquake of body wave magnitude about 4.5, which would typically yield at 15–20 km a site intensity of around VI on the MM scale. The Level 2 earthquake was taken as one with a return period of 2000 years, magnitude of 5.25 and site intensity of VII. For the Level 3 earthquake a frequency of 10^{-4} events/year, or a return period of 10^{-4} years, was taken, following NFPA guidance in NFPA 59A: 1980 on the design earthquake for LNG storage.

Earthquakes corresponding to each of these three levels were identified and the accelerograms of these earthquakes were obtained. The records used were those for the earthquake at New Madrid, Missouri, on 13 June 1975 (body wave magnitude 4.3), those for that at Forgaria-Cornino, Italy, on 11 May 1976 (magnitude 5.2) and the Temblor records of the earthquake at Parkfield on 27 June 1966 (magnitude 5.6).

The method of dynamic analysis used by Davies was described earlier.

Three generic types of liquefied gas storage were considered: a double skin cryogenic tank with a suspended roof, an inner shell of 9% nickel steel and an outer shell of mild steel to hold 20,000 te of LNG; a 1250 te capacity spherical pressure storage vessel to hold 1250 te of propane and a cylindrical pressure storage vessel, or torpedo, to hold 250 te of liquid carbon dioxide. For all three containments a foundation of hard rock was considered and the low temperature tank was also considered with a piled foundation on soft soil.

The failure modes considered were as follows. For the storage tank they were (1a) rupture of the connection between the tank wall and the floor; (1b) ripping of the tie-down strap; and (1c) excessive displacement of the base of the shell and rupture of the connection pipes. For the sphere they were (2a) tear at the connection of the shell and supporting leg; (2b) buckling of the support columns; and (2c) excessive displacement at the connecting pipe takeoff and rupture of the pipe. For the torpedo they were (3a) tear at the connection of the shell and support; (3b) rupture of straps or supports; and (3c) sliding on or rolling off support and rupture of the connecting pipes.

For the Level 1 earthquake the ratio of the seismic response stress to the seismic capacity stress was very small in each of these failure modes; the highest value of the ratio was 0.03 for the cryogenic tank tie-down strap on hard rock (mode 1b). For the Level 2 earthquake the ratio was 1.4 for the cryogenic tank tie-down strap on hard rock (1b), 0.48 for the inner shell base of the tank on hard rock (1a) and 0.21 for the inner shell base on piles (1a again). For the Level 3 earthquake these three latter values were 1.9, 0.72 and 0.29, respectively. Data on displacements are also given.

The conclusion of the study is that for liquefied gas storages of the type considered an earthquake which occurs sufficiently frequently to be likely to be felt during the life of the plant poses a negligible risk of loss of containment, but that one which approaches the maximum likely to occur in the United Kingdom could produce appreciable horizontal displacements in all types of plant and stresses in certain critical parts of some containments which exceed the dynamic design stresses allowed in current design codes.

A15.14.2 Seismic assessment of particular plants

An account of the seismic assessment of an existing process plant as part of the controls on acutely hazardous material (AHM) under the California Risk Management and Prevention Program (RMPP) under has been given by Ravindra (1992). The review covered both the site-specific geology and the engineering facilities.

He describes the investigation of the seismic characteristics of the site, including the impact of active faults; the potential for surface faulting and ground breakage, soil settlement and liquefaction, and slope instability; and local soil amplification. A seismic hazard curve was established.

The seismic capacity of the facilities was assessed by review of the design drawings and design codes used and by a walkaround of the plant.

It was found that some components had been designed using the static design method with an acceleration of 0.2 g; this acceleration is similar to that in the UBC. Detailed evaluation established that some of these items were vulnerable even though they had been designed to a building code.

The author gives examples of the seismic capacity assessed by a deterministic method given in RMPP guidelines and by the FA method and quotes values of the median ground acceleration A_{m} and the logarithmic standard deviation of the uncertainty in this acceleration. The failure mode determining seismic capacity in most cases is failure of the anchor bolts or anchorage. The author comments that generally this can be upgraded at minimal cost.

A15.14.3 Spherical pressure vessel

An assessment of the seismic capacity of a spherical pressure storage vessel has been described by D.W. Phillips (1982).

The vessel considered is a 15 m diameter vessel supported on 12 columns, or legs. The nominal contents of the vessel are 1200 te, the mass of the shell is 166 te and that of the legs 15.6 te. The active length of the supporting columns is 7.94 m. Each column has a flat steel plate welded to the bottom. The plate is attached by four foundation bolts to the concrete pedestal. The spacing between the bolts is 0.58 m and the inset of the bolts is 0.08 m. The bolts are 0.032 m in diameter. The effective dynamic mass of the vessel itself, with a contribution from the legs, is taken as 171 te ($166 + \frac{1}{3} \times 15.6$), giving a total effective dynamic mass of 1371 te for the full vessel.

From a separate study, it is known that the natural period of the vessel for horizontal vibration is as follows:

State	*Mass of vessel and shell* (te)	*Natural period* (s)
Full	1371	0.75
$\frac{1}{2}$ full	711	0.58
$\frac{1}{4}$ full	471	0.25

The vessel is located on a typical UK site. For such a site the seismic characteristics in terms of the free field horizontal acceleration are taken as

Return period (year)	*Horizontal acceleration* (g)
100	0.05
1000	0.12
10,000	0.25

The method of calculation used is essentially a static analysis, but first a dynamic analysis is conducted to determine a dynamic, or resonance, correction factor. For this use is made of the data given above on the natural period and the horizontal acceleration together with suitable response spectra. Two sets of response spectra are used, the NRC *RG 1.60* spectra and the Temblor–Parkfield spectra. A damping of 5% is taken as typical of welded steel at high strain and of bolted steel. For each degree of fill, the response spectra are used to obtain the acceleration from the natural frequency and damping. This value is scaled by the ratio of the maximum acceleration of the site to the maximum acceleration implied in the response spectra.

The results for the horizontal response with intact bracing are

Return period (year)	*Horizontal response* (g)					
	NRC response spectra			*Temblor–Parkfield reponse spectra*		
	Sphere full	*½ full*	*¼ full*	*Sphere full*	*½ full*	*¼ full*
100	0.07	0.11	0.14	0.11	0.16	0.21
1000	0.17	0.25	0.33	0.26	0.37	0.50
10,000	0.36	0.53	0.70	0.54	0.79	1.03

The accelerations are rather greater for the Temblor–Parkfleld than for the NRC response spectra. The greatest acceleration is experienced by the ¼ full tank, but for this case the mass is much less. The dynamic correction factor chosen is 2, which corresponds approximately to the ratio of the PGAs for the site to those for the case of the full tank with the Temblor–Parkfield spectra.

The sphere did not appear to have been designed for earthquake resistance. Probably, the principal horizontal force considered was wind loading. The relation for the wind load is

$$W_\mathrm{w} = C_\mathrm{D}\rho_\mathrm{a}\pi r_\mathrm{s}^2 u_\mathrm{w}^2 \qquad \text{[A15.14.1]}$$

where C_D is the drag coefficient, r_s the radius of the sphere (m), u_w the wind speed (m/s), W_w the wind load (N) and ρ_a the density of the air (kg/m^3). At the estimated Reynolds number of 10^7 the drag coefficient is 0.5. The wind speed with a 50 year return period would be between 18 and 32 m/s. Taking the higher value for the wind speed and $r_\mathrm{s} = 7.6$ m and $\rho_\mathrm{a} = 1.25$ kg/m^3

$$W_\mathrm{w} \approx 1.1 \times 10^5$$

The seismic loading is assumed to consist of accelerations in three orthogonal directions, two horizontal and one vertical. The vertical excitation is taken as ⅔ of the horizontal. The overall structural response is assumed to be given by

$$W_\mathrm{O} = \left[\sum_{i=1}^{3} W_i^2\right] \qquad \text{[A15.14.2]}$$

where W_i is the load in the ith direction (N) and W_O the overall load (N).

Then for the 100 year return period with horizontal acceleration of 0.05 g and incorporating the two orthogonal accelerations and the dynamic correction factor of 2, the peak horizontal seismic load of the full tank is

$$W_\mathrm{s} = 2^{1/2}(1371 \times 10^3) \times 2 \times 0.05 \times 9.81$$
$$\approx 1.9 \times 10^6 \mathrm{N}$$

Thus, the seismic load is nearly 20 times the wind load.

Phillips gives detailed calculations for the various modes of failure and for the corresponding seismic capacities. These show that the seismic response for which the structure is weakest is the overturning couple on the column supports. The corresponding failure mode is tensile failure of the pedestal bolts. For this failure mode the safety factor has the values of 0.5, 0.2 and 0.1 for the 100, 1000 and 10,000 year return periods, respectively.

The calculation of this failure mode may be summarized as follows. Figure A15.7 shows the overturning couple for which the relation is

$$F_\mathrm{sb} = \frac{1}{n} F_\mathrm{s} \frac{l_1}{l_2} \qquad \text{[A15.14.3]}$$

where F_s is the seismic load (N), F_sb the seismic tensile force on the bolts (N), l_1 and l_2 are the distances shown in Figure A15.7 (m) and n is the number of bolts resisting overturning. Taking $l_1 = 7.94$ m and $l_2 = 0.66$ m and using the seismic load for the 100 year return period

$$F_\mathrm{sb} = \frac{1}{24}(1.9 \times 10^6) \times \frac{7.94}{0.66}$$
$$= 9.5 \times 10^5 \mathrm{~N}$$

Taking a bolt area of 8.0×10^{-4} m^2 per bolt gives a bolt tensile stress of

$$F_\mathrm{sb} = \frac{9.5 \times 10^5}{8.0 \times 10^{-4}}$$
$$= 1.2 \times 10^9 \mathrm{~Pa}$$

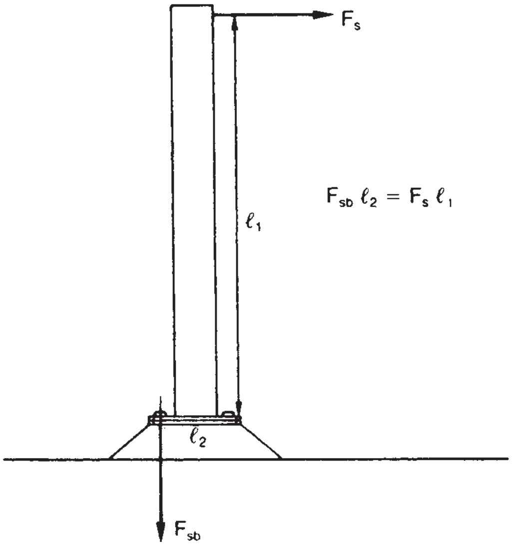

Figure A15.7 *Overturning couple on the support column of a pressure storage sphere (Phillips, 1982) (courtesy of the ukaea Systems Reliability Directorate)*

where F_{sb} is the seismic tensile stress on each bolt (Pa). For the purpose of this assessment, tensile failure is assumed to occur at the yield stress, which for high tensile steel is some $0.6-0.7 \times 10^9$ Pa. Taking the lower value of the yield stress, gives for the safety factor at the 100 year return period a value of 0.5 ($= 0.6 \times 10^9 / 1.2 \times 10^9$).

For none of the other failure modes considered was the safety factor less than unity at the 100 year return period, though for two others it fell to unity at the 1000 year return period and below it at the 10,000 return period.

A15.14.4 Storage tank

An assessment of the seismic capacity of a flat-bottomed storage tank has been described by R.P. Kennedy (1989). The tank considered is 40 ft in diameter with a shell 37 ft high and an overall height to the tank top of 43.4 ft.

The author describes in detail the use of the CDFM method. This consists of two parts, the determination of the seismic responses and the determination of the seismic capacities. There is not necessarily a one-to-one correspondence between a seismic response and seismic capacity. For a given response there may be several features resisting failure and all these must be considered.

The following responses are considered: (1) overturning moment in the tank shell immediately above the base plate of the tank; (2) overturning moment applied to the tank foundation through a combination of the tank shell and base plate; (3) base shear beneath the tank base plate; (4) combination of the hydrostatic plus hydrodynamic pressures on the tank side wall; (5) average hydrostatic minus hydrodynamic pressure on the base plate of the tank; and (6) fluid slosh height. These responses are all expressed as forces except the last; for this what matters is whether the sloshing fluid hits the roof.

The author comments that the first of these responses is usually the governing one. The third is seldom governing for tanks with a radius greater than 5 m. The second, fourth and sixth seldom govern.

In investigating these responses at least two horizontal modes, the impulse and the convective, or sloshing, modes and one vertical mode should be considered.

Kennedy gives detailed calculations for the various seismic responses and for the corresponding seismic capacities. The governing response is usually the first, the overturning moment in the tank shell.

The seismic responses are determined using a value of 0.27 g for the peak ground acceleration. The overturning moment response is then estimated as 19,600 kip-ft. The corresponding capacity is determined by considering (1) the compressive buckling capacity of the shell; (2) the tensile hold-down capacity of the anchor bolts, including their anchorage and attachment to the tank; and (3) the hold-down capacity of the fluid pressure acting on the tank base plate. The combined resistance of these gives an overturning moment capacity of 20,800 kip-ft. The SME for this response is then calculated as 0.29 g (0.27 x (20,800/19,600)).

This response gives the lowest value of the SME and the overall SME for the tank is thus determined as 0.29 g.

Kennedy also describes the determination of the seismic capacity in terms of the alternative FA method. Using this method the SME is found to be 0.31 g.

A15.15 Notation

a	peak ground acceleration (fraction of g); (cm/s^2) (Sections A15.2 and A15.6 only); (m/s^2) (Sections A15.8 and A15.10 only)
a, a'	constants in Equations A15.2.10 and A15.11.2, respectively
A	maximum amplitude of earthquake (mm)
A_m	median ground acceleration (fraction of g)
A_O	maximum amplitude of standard earthquake (mm)
b, b'	constants in Equations A15.2.10 and A15.11.2, respectively
c	damping coefficient (kg/s)
C	coefficient (Equation A15.9.1)
C	flexibility factor
C_D	drag coefficient
d	peak ground displacement (cm)
E	energy of earthquake (erg)
F	force (N)
F_s	seismic force (N)
F_{sb}	seismic tensile force on bolts (N)
F_{sb}	seismic tensile stress on bolts (Pa)
g	acceleration due to gravity (m/s^2)
h	focal depth (km)
H	depth of soil layer (m)
I	intensity of earthquake (Equation A15.11.5)
I	occupancy importance factor (Equation A15.9.2)
I_O	epicentral intensity of earthquake
k	modifying factor for focal distance (km) (Equation A15.2.2)
k	resistance (kg/s^2) (Equations A15.10.2–5)
K	framing factor
l_1	active distance of support column (m)
l_2	spacing + inset of bolts on support column base plate (m)
m	mass (kg)
m_b	body wave magnitude of earthquake
M	magnitude of earthquake

M_L	local magnitude of earthquake
M_S	surface wave magnitude of earthquake
n	number of bolts resisting overturning
N	frequency of earthquake (year^{-1})
P	annual probability of exceedance
r	epicentral distance (km)
R	focal distance (km)
S	site factor
S_a	spectral acceleration (m/s^2)
S_d	spectral displacement (m)
S_v	spectral velocity (m/s)
t	time (s)
T	natural period (s)
T	natural period of soil layer (s) (Equation A15.7.1)
u_w	wind speed (m/s)
v_s	velocity of shear wave (m/s)
V	horizontal force, base shear (N)
V	response function (m/s) (Section A15.10 only)
W	load (N)
W_i	load in ith direction (N)
W_O	overall load (N)
W_s	seismic load (N)
W_w	wind load (N)
x	displacement (m)
Z	seismic risk zone factor
β	composite variability (fraction of g)
β_R	log-normal standard deviation of randomness of median ground acceleration (fraction of g)
β_U	log-normal standard deviation of uncertainty in median ground acceleration (fraction of g)
ζ	damping factor
λ	average annual number of events
ρ_a	density of air (kg/m^3)
ω	damped frequency (s^{-1})
ω_n	natural frequency (s^{-1})

Subscripts

D	damping
I	inertia
max	maximum value
S	elastic

Appendix 16

San Carlos de la Rapita

Contents

At about 14.30 in the afternoon of 11 July 1978 fire and explosions from a road tanker carrying propylene occurred at a camp site at Los Afaques (The Sand Dunes) at San Carlos de la Rapita between Barcelona and Valencia in Spain. The eventual death toll was 215.

A Court of Inquiry on the disaster was held at Tarragona (Court of Inquiry, Tarragona 1982). A report was submitted to the inquiry by Carrasco (1978). Independent investigations for the HSE were been carried out by Scilly (1978) and Hymes (1983 SRD R275), for the Hampshire Fire Brigade by Stinton (1978, 1979, 1983) and for the Dutch Directorate General of Labour by Ens (1986 LPB 68). Analyses of the accident are given by V.C. Marshall (1985, 1986 LPB 72, 1987).

Selected references on San Carlos are given in Table A16.1.

A16.1 The Camp Site

The camp site was a triangular shaped piece of land between the coast road and the sea some 3 km from the nearest township San Carlos de la Rapita to the north. It was 200 m in length and 10,000 m^2 in area, tapering from about 100 m wide at the north to 30 m at the south end, and 60 m wide at the point of the accident. There was a brick wall on a concrete foundation between the road and the camp.

On the day of the accident, the camp site was fully booked with some 800 people, but not all these were there at the time and in the area affected. Estimates of the number on site and of the number in the area most affected are 500 and 300–400, respectively.

A16.2 The Road Tanker

The road tanker was manufactured in 1973. It had no pressure relief valve and no pressure test certificate. It had nominal and actual capacities of 45 and 44.4 m^3.

It has been alleged that the tanker had been used on previous occasions to carry ammonia, which can lead to cracking of the tank, but this has been denied.

At 12.05 the tanker took on a load of propylene at the ENPETROL Tarragona refinery. The system was that the driver would learn how much he was carrying when the vehicle was weighed at the weighbridge. There was no metering or other device to prevent overfilling. If he wished to reduce the load, he could burn some off using a device like a flamethrower. The maximum load for the vehicle was 19 te, but it was plated as suitable for a maximum load of 22 te and it was actually weighed out as a 23.5 te load. At 12.35 the vehicle left the refinery.

The driver had a recommended route, which was the motorway, and was provided with the toll money, but actually took the N340 coast road, which went past the Los Alfaques camp.

A16.3 The Fire and Explosions – 1

The sequence of events at the camp site is not entirely clear, but several eyewitness accounts are available. V.C. Marshall (1987) quotes the following. A young man serving a customer in the camp shop off the main site heard a bang. He got into his car to investigate and 2 min after the first sound heard a severe explosion. A 'fireball' appeared on the site. A tourist in the camp restaurant heard a 'pop' from a tanker on the main road and saw a milky cloud drifting towards him. He ran to move his car and seconds later the cloud ignited. In one newspaper account a motor cyclist following the vehicle said that smoke and fire were issuing from the tank. In another such account a tourist walking his dog at the camp site entrance saw the tanker start to snake and then tip over; there followed almost immediately an explosion and fire.

There were conflicting reports on the last movements of the road tanker, summarized by Hymes (1983 SRD R275). They include reports to the effect that the driver stopped at the camp with the tanker already leaking; that he stopped after it sprang a leak with a sharp report at the camp; that the vehicle veered across the road and broke through the camp site wall, suffering either a small leak or complete disintegration; and that the tanker veered across the road and struck the wall a glancing blow.

Hymes gives two photographs, the first captioned as showing the unignited gas cloud and the second the cloud on fire. The latter photograph is shown in Figure A16.1. The photographer stated that the time between taking his first picture and going to the camp entrance to take further shots was 1–2 min and that the tanker ruptured violently after a few minutes.

It is reported that until the main 'fireball' event, people stood around watching the pall of smoke from the fire. When it did occur large numbers, many scantily clad, were burned, some running into the sea to escape or douse the flames.

Figure A16.1 *The fire preceding the 'fireball' at San Carlos (Hymes, 1983 SRD R275) (Courtesy of the Safety and Reliability Directorate)*

The area of damage and injury, including injury outside the flame envelope, is quoted by Marshall as covering an area equivalent to that of a 125 m radius circle. Over 90% of the camp site was gutted by fire.

The explosion effects were variable. The discotheque about 75 m from the tanker was completely demolished, probably by an explosion of the gas inside it, killing four people, but in the opposite direction at a distance of only 20 m a motor cycle still stood on its footrest. Many other objects in the camp liable to be blown over by blast still stood.

The site after the event is shown in Figure A16.2.

The vehicle was torn into four main pieces. Some two-thirds of the tank, including the rear portion, flew to the north-west, landed on the ground some 150 m away and then slid and came to rest in the outer wall of a restaurant about 300 m from its starting point. The middle section travelled about 100 m to the north-east into the camp. The cab unit travelled some 60 m along the line of the road to the south. The front end cap fetched up about 100 m beyond the cab. The location of some of the fragments is shown in Figure A16.3. The front end cap is the white hemispherical object at the bottom of Figure A16.3.

A16.4 The Emergency and the Aftermath

For about half an hour after the fire there were some 200–300 people milling round the camp, many seriously burned and calling for help. Private cars and taxis began to ferry the injured to a hospital at Amposta 13 km away. The first ambulance came at 14.45 from the Shell oil drilling site at San Carlos. The municipal ambulances came at 15.05 and the fire brigade about 15.30.

The road was still blocked by the burning cab so that victims had to be rescued from both sides of the camp and taken north to Barcelona or south to Valencia as circumstances permitted. Those taken north to Barcelona received primary medical care at points en route, while those taken south to Valencia 165km away did not. In the first week the death rate at Valencia was twice that at Barcelona, but over 2 months the death rates evened up, since most victims were too badly burned to survive.

Over 100 people died outright. Others died later from burns, so that the final figures were 215 dead and 67 injured.

Most of those treated had very serious burns. Out of 148 cases 122 had third degree burns to 50% or more of the body. Either there were fewer people only slightly burned or they received treatment elsewhere.

A16.5 The Fire and Explosions – 2

The Court of Inquiry held that there had been a rupture of the road tanker due to hydraulic overfill. This was the explanation given in a report submitted to it by Carrasco (1978).

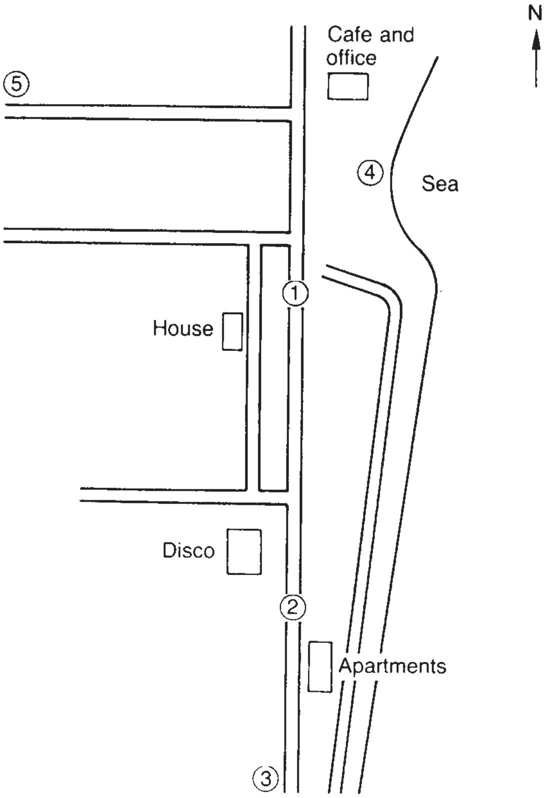
Other authors have put forward alternative explanations. There appear to be three principal hypotheses concerning the initial event: (1) hydraulic rupture of the tank, (2) a small leak on the tank and (3) a road accident.

A version of the second hypothesis has been described by Hymes (1983 SRD R275). This is that a leak occurred on the tanker, that a gas cloud formed and found a source of ignition and that the flames burned back to the tanker. There followed an engulfing fire which caused a BLEVE. The vessel was in a weakened condition and the time for the BLEVE to occur was shorter than usual. Hymes does not state how the tanker came to stop at the camp, but on this scenario it could have been to attend to the leak.

A somewhat similar account is given by Stinton (1983).

The starting point in the argument in favour of the third hypothesis, as developed by Ens (1986 LPB 68), is the need to explain how the tanker came to stop and how the tank itself failed. Relevant here is the evidence of the one eyewitness who saw smoke and flames coming from the tanker and of the other who saw it snaking. The hypothesis is as follows. The tanker was grossly overfilled and under stress

Figure A16.2 *The site after the fire and explosion (Hymes 1983 SfiD R275). The camp site is in the right background behind the breached wall (Courtesy of the Safety and Reliability Directorate)*



1 Apparent point of disintegration

5 Rear end of tank

Figure A16.3 *Flight of some missiles generated by the explosion (after Stinton, 1983; V.C. Marshall, 1987)*

so that it was liable to burst if subjected to impact. It crashed due to a driver failure or tyre defect, causing it to break through the boundary wall into the camp site. The tank ruptured and released its contents. A gas cloud and liquid pool formed, the gas being at first too rich to burn rapidly. In due course, however, the heat vaporized the liquid pool and there was a fireball. Minor explosions may have occurred at the edges of the cloud and stronger explosions in the buildings.

With regard to the first hypothesis, that the tank suffered hydraulic rupture, attention has focused on the overfilling of the tanker and on the possible effects of this. The calculations on this aspect are very dependent on the assumptions made about the volume and temperature of the liquid when the tanker left the refinery.

Evidence was presented by Carrasco (1978) that the tank contents could have warmed up sufficiently in 2½ h for the tank to become hydraulically full. He estimates a warm-up rate of 5.6°C/h.

Carrasco's work has been criticized by Marshall and Ens. Marshall draws attention to the work of Moodie (1982) showing the need, in considering hydraulic rupture, to allow for the expansion of the tank metal, the expansion being equivalent to between 3 and 6°C, depending on the steel used. Both authors, however, consider that it is possible that the tank had become hydraulically full. Ens suggests that this becomes credible if allowance is made for a difference between nominal and actual tanker capacity, weighing errors and warming up of the liquid in the terminal pipework. Under such biaxial stress the material would no longer be ductile but would become brittle.

V.C. Marshall (1987) gives an extensive discussion of the possible warm-up of the tank, the hydraulic overfill and physical rupture, the behaviour of the fragments and the fire. Despite his critique of Carrrasco, he concludes that hydraulic rupture of the tank is the most likely cause of the incident.

He suggests that the initial bang heard was probably the tank rupture, that the later explosion was of gas which had entered a building and then exploded inside it and that the fire was a severe flash fire rather than a vapour cloud explosion or a BLEVE. The pattern of injuries, with a large proportion of dead to injured, is consistent with a flash fire.

Hymes, Ens and Marshall all give detailed accounts of the site and of the physical evidence such as the fragments, the explosion damage and the burned area.

A16.6 Lessons of San Carlos

Among the lessons of San Carlos are the importance of

(1) Equipment, procedures, supervision and training to prevent overfilling of vehicles carrying hazardous materials.
(2) Provision of pressure relief on vehicles carrying flammable materials.
(3) Routing of vehicles carrying hazardous materials away from populated areas and vulnerable targets.
(4) Prompt treatment of burn victims.

Appendix 17

ACDS Transport Hazards Report

Contents

A17.1 The Investigation

The Advisory Committee on Major Hazards in its *Third Report* (Harvey, 1984) recommended that although its terms of reference were restricted to fixed installations, the major hazard potential from the transport of hazardous materials should also receive attention.

The HSC accordingly asked the relevant permanent committee, the Advisory Committee on Dangerous Substances (ACDS) to examine the matter. Its findings are presented in *Major Hazard Aspects of the Transport of Dangerous Substances* (ACDS, 1991) (the ACDS *Transport Hazards Report*).

Selected references on the ACDS *Transport Hazards Report* are given in Table A17.1. Its principal contents are shown in Table A17.2.

Some of these entries are paraphrased.

A17.2 Substances and Activities

The study deals with four main transport activities: (1) rail transport, (2) road transport, (3) marine transport (ports only) and (4) explosives.

The substances investigated varied as between these different modes of transport. For road and rail four substances were studied: (1) motor spirit, (2) LPG, (3) chlorine and (4) ammonia. These substances are referred to in the report, and therefore here, as the non-explosive materials.

For ports the substances considered were (1) flammable liquids, (2) flammable liquefied gas, (3) toxic liquefied gas, (4) ammonia and (5) ammonium nitrate.

The transport of explosives by rail and by road was the subject of a separate study within the report.

Excluded from the study were air transport, pipelines and radioactive substances.

A17.3 Event Data

The report contains a wealth of data on the movement of hazardous materials by rail, road and sea, on the nature and composition of loads and cargos and on event frequencies and probabilities.

The event frequencies cover not only land transport accidents such as vehicle and wagon impacts and fires and marine accidents such as collisions, strikings, groundings and engine room fires but also data used in the various fault trees.

The probability data include release size distributions, ignition probabilities and so on.

A17.4 Hazard Models

The study makes use of hazard models for fire, explosion and toxic release.

The fire models are for (1) a torch fire, (2) a flash fire and (3) a pool fire and the explosion models are for (1) a vapour cloud explosion (VCE), (2) a BLEVE and (3) a condensed phase explosion. The models relevant to toxic release are those for gas dispersion.

The pool fire model is required for motor spirit, the other fire models and the VCE and BLEVE models for LPG or LFG.

The hazard models fall into two sets. The first set comprises HSE models, which are used for rail and road transport, the second set models incorporated in the SAFETI code, which are used for ports. In the following account the HSE models are described first, followed by those used in SAFETI, where applicable.

A17.4.1 Gas dispersion

The gas dispersion models used are DENZ and CRUNCH for instantaneous and continuous releases, respectively. The main direct application of these models is to toxic release.

Use is also made of the parameterizations by Considine and Grint (1985) of results for flammable gas clouds obtained from DENZ and CRUNCH.

The gas dispersion model used in SAFETI is the dense gas dispersion model of R.A. Cox and Carpenter (1980).

A17.4.2 Torch fire

The torch, or jet, fire model used is that of Considine and Grint (1985), modified to give length and width and representing the flame as a cone.

Atmospheric transmissivity is determined by the method of Simpson (1984 SRD R304).

A17.4.3 Flash fire

For a flash fire use is made of the model of Considine and Grint (1985). The formation of the gas cloud is modelled using the gas dispersion models described in Section A17.4.1 and its combustion by assuming that it burns within the contour of the lower flammability limit.

A17.4.4 Pool fire

For a pool fire use is made of the SPREAD model, a sister model of SPILL (Prince, 1981 SRD R210), which differs from the latter in treating simultaneously the spreading and burning of the pool. The regression rate used is that of Mitzner and Eyre (1982). The other features of the model are not described but are evidently conventional.

A17.4.5 Vapour cloud explosion

The treatment of a VCE involves the determination of the mass of fuel in the cloud and of the overpressure resulting from explosion of this fuel.

For the mass of fuel in the cloud, for an instantaneous release the method is to take this mass as twice the flash fraction. It is assumed that no explosion occurs if the mass is less than 10 te. For a continuous release the mass of fuel in the cloud is determined by the method of Considine and Grint (1985).

The overpressure from explosion of this mass of fuel is determined from the correlation of Kingery and Pannell (1964) between mass of explosive and peak overpressure for TNT. The implication is that a TNT equivalent model is used, but further details are not given.

The VCE model used in SAFETI is the TNO correlation model.

A17.4.6 BLEVE

The BLEVE model used is that of A.F. Roberts (1981/82).

A17.4.7 LPG fire model

The hazard models described are used in conjunction with the release scenarios for rail and road transport to produce an overall LPG fire model.

In this overall model the number of fatalities is obtained from the relation

$$N = D[aP_{\mathrm{od}} + bP_{\mathrm{id}}P_{\mathrm{f}}|_{\mathrm{id}} + cP_{\mathrm{id}}(1 - P_{\mathrm{f}}|_{\mathrm{id}}) + d] \qquad \text{[A17.4.1]}$$

where D is the population density (persons/m^2), N the number of fatalities, $P_{\mathrm{f}|\mathrm{id}}$ the probability of fatal injury given that the person is within the cloud, P_{id} the probability of being indoors, P_{od} the probability of being outdoors and a–d are coefficients. The coefficients c and d are associated with VCEs.

The model is shown in Table A17.3 in the form of the coefficients a–d to be used in Equation A17.4.1.

A17.4.8 LPG fire scenarios

The LPG fire models just described are applied in the report to yield the hazard ranges and areas for the set of scenarios relevant to rail and road transport. These are summarized in Table A17.4.

A17.4.9 Condensed phase explosion

The condensed phase explosion model applicable depends on the type of explosive. This aspect is discussed in Section A17.10. An HD1.1 explosive constitutes a mass explosion hazard, an HD1.2 explosive a projection, or fragmentation, hazard and an HD1.3 explosive a fire hazard.

For the estimation of the overpressure from an HD1.1 explosive use was again made of the correlation of Kingery and Pannell (1964).

For the fragments from an HD1.2 explosive data were supplied by the MoD from explosives trials, which allowed an estimate to be made of the density of fragments possessing a kinetic energy in excess of 80 J, taken as the lethal value. From these data two graphs were constructed, one for persons outdoors and one for those indoors. The data are classified as confidential but the report states that the average probability of fatal injury so obtained for persons in the open at 200 m is 0.02, while that for those indoors at the same distance is an order of magnitude less.

The model used for the fire on an HD1.3 explosive is a vertical flame. Further details are not given.

Table A17.3 *Coefficients for LPG hazard model fatal injury equation (Advisory Committee on Dangerous Substances, 1991) (Courtesy of HM Stationery Office)*

	a	b	c	d

20	76	12	110	175
40	96	15	160	245

F BLEVEs (road tankers)

Vessel capacity	*Fireball radius* (m)	*Fireball duration* (s)	*Distance to 50% lethality* (m)	*Distance to 1% lethality* (m)
15	69	11	95	150

[a] This is also the distance to spontaneous ignition.

[b] Cloud radius 75 m.

A17.4.10 Condensed phase explosion: hazard range

It is convenient to give at this point the estimate quoted in the report of the hazard range of a condensed phase explosion.

The ranges for fatal injury by thermal radiation or overpressure are in practice about 80–85 m, being limited by the maximum permitted loads of explosive of 16 te for a lorry and 20 te for a rail wagon. These are the distances at which the proportion of fatal injuries would be about 5%.

A17.4.11 Toxic release

For toxic release use is made of the appropriate gas dispersion model to determine toxic concentration and hence, for a particular exposure period, the corresponding toxic load.

The conventional infiltration model is used to determine the indoor toxic load.

For the number of persons affected by the release, the general approach is that used in the impact model described in the next section. The concentration contours are calculated at which the probabilities of fatal injury are 1.0, 0.9, 0.5 and 0.1. This gives between these isopleths three zones with concentrations denoted C_1, C_2 and C_3 and with average probabilities of fatality taken as 0.95, 0.3 and 0.1.

For each zone there is a corresponding probability of escape indoors, the values used being 0 for C_1, 0.2 for C_2 and 0.8 for C_3.

An analysis is given of the possible responses of an individual affected by a toxic gas cloud. The results are shown in Figure A17.1.

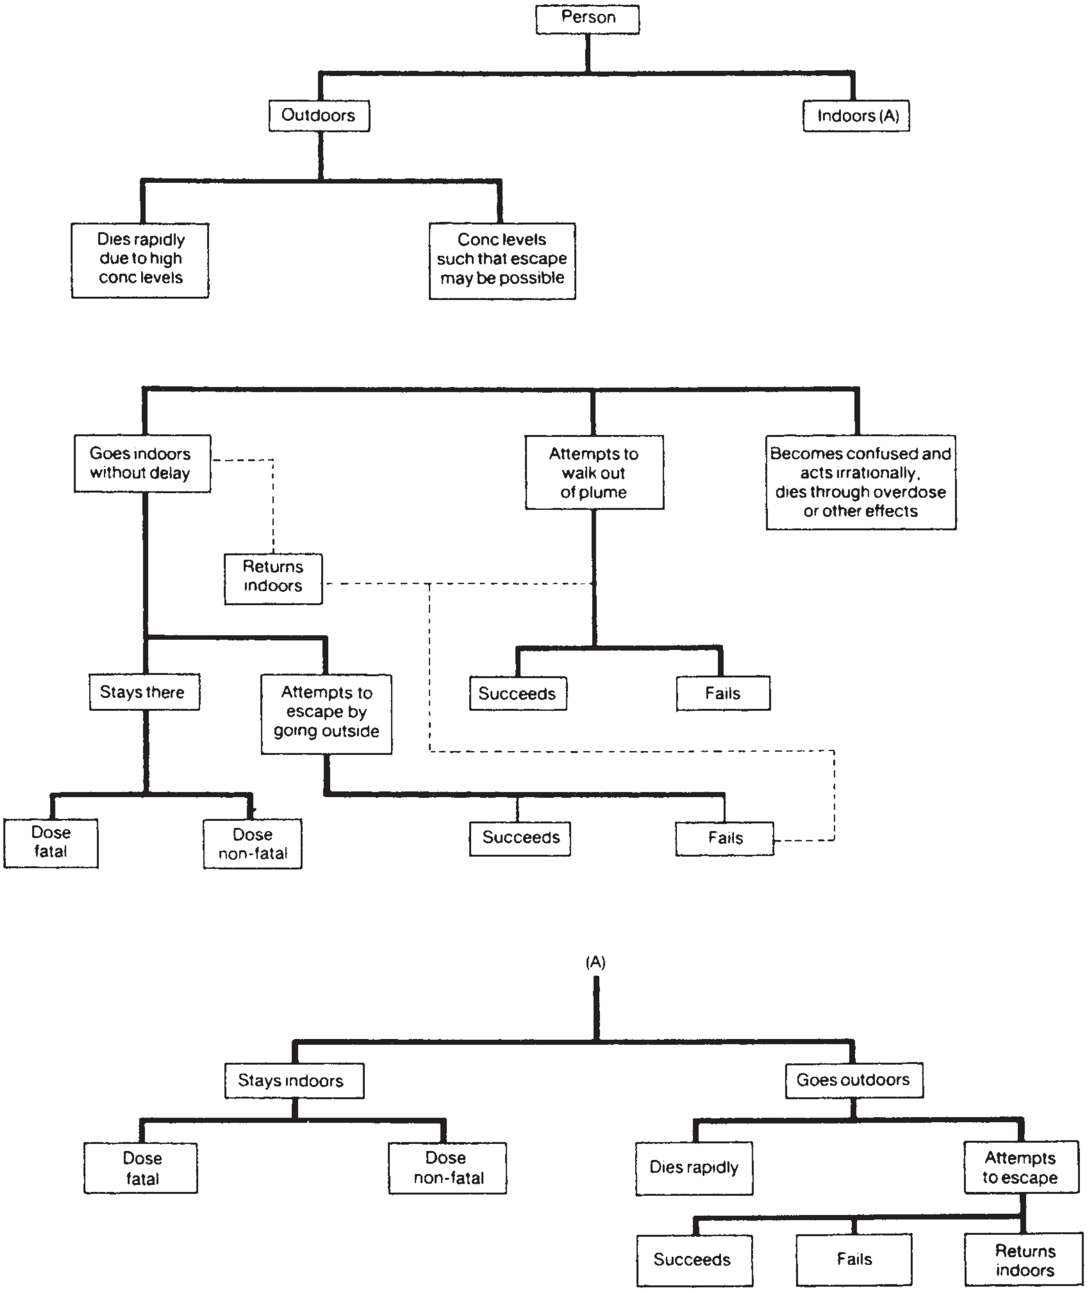

Figure A17.1 *Possible responses of an individual affected by a toxic gas cloud (Advisory Committee on Dangerous Substances, 1991) (Courtesy of HM Stationery Office)*

A17.5 Injury Relations

Injury models are used in the study to relate the intensity of the physical effects to the probability of injury. These are mainly probit equations, but HSE dangerous doses are also utilized. Some use is also made of rules-of-thumb.

The injury relations fall into two sets. The first set comprises HSE models, which are used for rail and road transport, the second set relations incorporated in the SAFETI code, which are used for ports. In the following account the HSE relations are described first, followed by those used in SAFETI, where applicable. In some cases no details are given for the latter; where this is the case, it should not be assumed that they are the same as the HSE relations.

A17.5.1 Thermal radiation

For fatal injury from thermal radiation use is made of the probit equation of Eisenberg, Lynch and Breeding (1975)

$$Y = -14.9 + 2.56 \ln(I^{4/3}t) \qquad [A17.5.1]$$

where I is the thermal radiation (kW/m^2), t the time (s) and Y the probit.

In the SAFETI work on fireballs from hot rupture of large cargos in port, a modification of the Eisenberg equation was used. In the region of thermal radiation above 500 kJ/m^2, it was assumed that 75% of persons outdoors and 25% of those indoors are killed, either by radiation or by secondary ignition effects.

A17.5.2 Fire engulfment

Injury can also occur due to engulfment in a fire. The assumptions made are that a person outdoors is killed, but that for a person indoors there is a certain probability of survival with the complementary probability $P_{\mathrm{f|id}}$ of becoming a fatality.

In the SAFETI work the assumptions made were that for a flash fire all persons outside within the LFL contour and 30% of those indoors within the contour are killed but that no fatalities occur beyond this contour.

A17.5.3 Explosive: explosion overpressure

An HD1.1 explosive constitutes a blast hazard. For fatal injury two equations are given, the first being used in the road and rail transport study and the second, and more up-to-date, in the port study, reflecting developments as the work progressed.

The relationship given is for fatalities amongst persons indoors and is based on data on fatal injuries from V-2 rockets in the Second World War, with allowance for the effect of bomb shelters. In this situation building collapse is a more significant cause of injury than overpressure. The data are shown in Figure A17.2(a). The relation is applied also to persons outdoors in the built-up area and therefore near to buildings.

The first version of the equation is

$$Y = 1.47 + 1.37 \ln p^{\mathrm{o}} \qquad [A17.5.2]$$

where p^{o} is the peak side-on overpressure (psi) and Y the probit. The second version is

$$Y = 2.47 + 1.37 \log_{10} p^{\mathrm{o}} \qquad [A17.5.3]$$

A17.5.4 Explosive: explosion fragments

The hazard from an HD1.2 explosive is fragments. As stated in the previous section, the lethality of a fragment is taken as a function of its kinetic energy, and thus of mass and velocity, the lethal value being taken as one in excess of 80 J.

A17.5.5 Explosive: thermal radiation

The hazard from an HD1.3 explosive is thermal radiation. Figure A17.2(b) shows the relationship given in the report for this.

A17.5.6 Chlorine toxicity

For fatal injury from exposure to chlorine use is made of the following probit equation:

$$Y = -4.4 + 0.52 \ln(C^{2.75}t) \qquad [A17.5.4]$$

where C is the concentration of chlorine, t the exposure time and Y the probit.

A17.5.7 Ammonia toxicity

For fatal injury from ammonia the probit equation used is

$$Y = -12.2 + 0.8 \ln(C^2t) \qquad [A17.5.5]$$

where C is the concentration of ammonia, t the exposure time and Y the probit.

The SAFETI code uses for fatal injury from ammonia the probit equation.

$$Y = -9.82 + 0.71 \ln(C^2t) \qquad [A17.5.6]$$

where C is the concentration of ammonia (ppm), t the exposure time (s) and Y the probit. The group (C^2t) is actually computed as the time integral of the square of the concentration.

A17.5.8 Hazard impact

The method principally used in the report to estimate the impact of the hazard is as follows. The ranges are determined at which the physical effect is lethal at the 0.90, 0.50 and 0.10 probability levels. The areas within these contours are denoted A_{90}, A_{50} and A_{10} respectively. The average lethality within each area is taken as the average of the lethalities at the bounding contours.

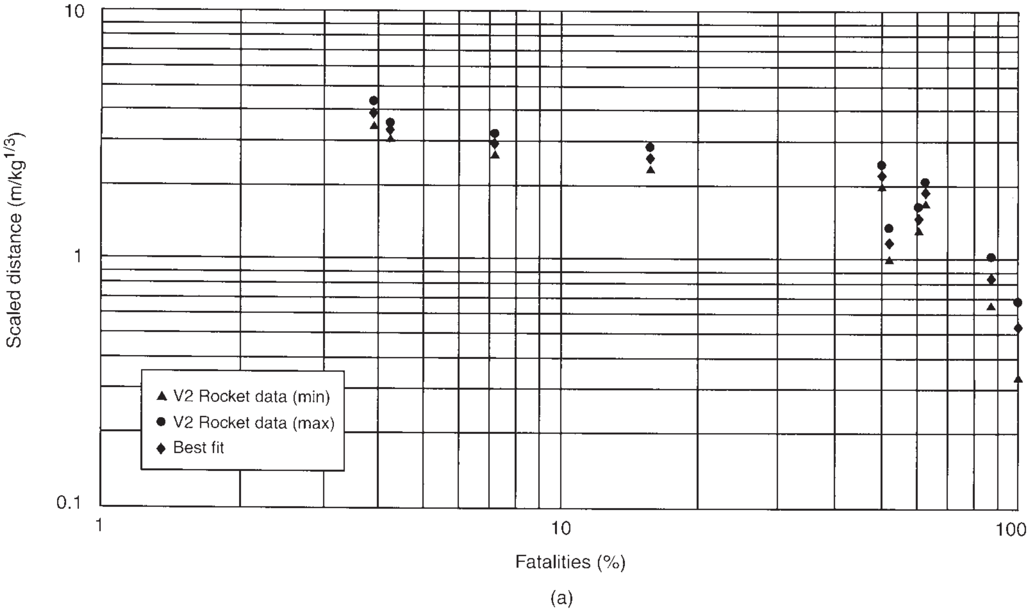
Thus, the lethality with the circle A_{90} is 0.95 (= (1.0−0.90)/2), that within the annulus (A_{50}−A_{90}) is 0.7 and that within the annulus (A_{10}−A_{50}) is 0.3. This yields the hazard impact relation

$$N = D[0.95A_{10} + 0.7(A_{50} - A_{90}) + 0.3(A_{10} - A_{50})] \qquad [A17.5.7]$$

where A is an area (m^2), D the population density (persons/m^2) and N the number of fatalities. Use is also made of variations on this basic equation.

A17.6 Population Characteristics

In transport scenarios the characterization of the population exposed tends to be much more complex than for fixed installation scenarios. A significant proportion of the modelling described in the report is addressed to this aspect.



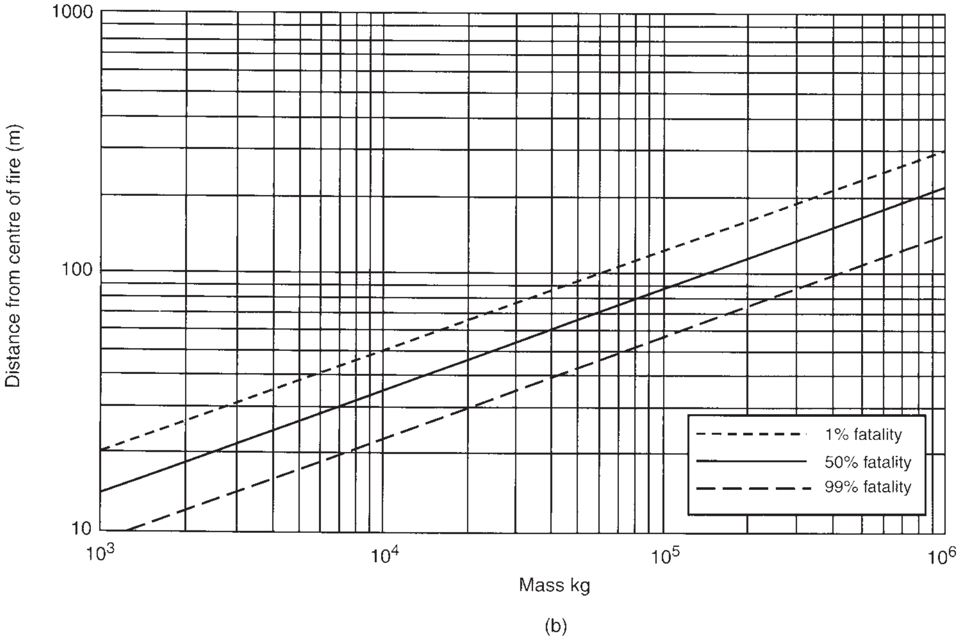


Figure A17.2 *Hazard ranges for explosives (Advisory Committee on Dangerous Substances, 1991): (a) HD1.1 explosive (mass explosion hazard) and (b) HD1.3 explosive (fire hazard) (Courtesy of HM Stationery Office)*

For the general population the report utilizes four categories of population density. These are 4210, 1310, 2120 and 20 persons/km^2.

The proportion of the general population outdoors is taken for the purposes of the assessment as a function of the meteorological conditions, particularly conditions D5 and F2.

This characterization of the general population essentially suffices for the assessment of fixed sites such as marshalling yards and ports but needs to be supplemented by additional models for rail and road transport. These models, which are described below, are relatively complex but this complexity is necessary to obtain a realistic estimate of the risks.

A17.7 Rail Transport

The hazard of rail transport of non-explosive materials is considered in Appendix 8 of the report.

An account has been given in Chapter 23 of the rail transport environment in the United Kingdom. It includes data given in the ACDS report on tank wagon capacities and movements and on release frequencies and probabilities.

A17.7.1 Wagons and movements

For the four hazardous materials studied, the rail tank wagon capacities and movements are given in Table 23.23. The wagon capacities are for motor spirit 32 and 75 te, for LPG 20 and 40 te, for chlorine 29 te and for ammonia 53 te.

Rail movements along the major routes in the United Kingdom in 1985 are shown in Table A17.5, which also gives the population densities.

A17.7.2 Exposed population

The population exposed to an en route rail accident considered in the report are the personnel on the trains involved, the passengers in passenger trains (PTs) and the general off-track population.

For the density of the general population along the track the basic method used was to use a map to assign each square kilometre of the trackside area to one of the four population densities described in Section A17.6.

A check was made on the adequacy of using these generalized values by taking one of the rail routes and determining the population densities with circles of 300 m radius along the track from the 1981 Census enumeration districts. The process was repeated with circles of smaller and larger diameter. The results showed that in general the map and census methods gave similar results, except that the map method underestimated the urban population in a few places.

For the exposure of passengers in a PT to hazard from a heavy goods trains (HGT) five basic scenarios are considered. One is the involvement of a PT waiting at a stop signal in the hazard zone of a release from an HGT, the obedient train case. The other four are (1) collision of the PT and HGT, causing a release; (2) collision of a PT and an HGT, where a release has already occurred; (3) a PT entering the hazard zone of a release from an HGT and (4) a PT entering the hazard zone of a release from an HGT and colliding, causing a further release. Two wind conditions are considered: (1) wind along the track and (2) wind perpendicular to the track.

The proportion of carriages in the PT involved is the ratio of the length of the hazard-affected zone to the length of the train.

With regard to air infiltration into a PT, the ventilation on most modern trains is controlled from the driver's cab and is set at about 13 air changes/h. The driver experiences a ventilation rate about six times this and is thus effectively out of doors.

A17.7.3 Initiating events and event frequencies

The report considers two main types of initiating event.

These are puncture of a tank wagon by collision or derailment and failure or maloperation of the tank wagon equipment.

The treatment given for the frequency of these events for each of the four substances and for the probability of

Table A17.5 *Rail traffic and population densities along some major routes in the United Kingdom in 1985 (Advisory Committee on Dangerous Substances, 1991) (Courtesy of HM Stationery Office)*

	Motor spirit	*LPG*	*Ammonia*	*Chlorine*
All movements (wagon km/year)	10,199,095	1,390,590	1,348,080	313,668
Total wagon journeys/year	55,814	4,334	4,500	2,342
Major route	Merseyside–Leeds–Humberside	Hampshire–Midlands	Teeside–Scotland	Merseyside–Anglesey
Route length (km)	223	329	262	156
Number of wagons on route/year	5300 × 32 te 3900 × 75 te	1,323	2,204	1,216
Wagon km/year on route	2,051,600	435,267	530,288	189,696
% Traffic in that substance	20	31	39	60
Population density (people/km^2)	*Aggregate length of route with that population density*			
Urban (4210)	15	30	12.5	0
Both sides[a]				
Suburban (1310)				
Both sides[a]	36.5	48	40.5	19
One side only[a]	1.5	20	12.5	24

Tunnel	9.5			

[a] Indicates whether the population is on both sides of the railway or on one side only, the other side being rural.

ignition, immediate or delayed, of flammables is described in Chapter 23.

A17.7.4 Motor spirit events

For motor spirit, the scenarios considered are instantaneous releases of 32 and 75 te and continuous releases of 25 kg/s (equivalent to a 100 mm hole).

A release of motor spirit, if ignited, results in a pool fire. The pool spread and fire model used is described in Section A17.4.

For a continuous release the times for the 32 te and 75 te wagons to empty are approximately 20 and 50 min, respectively. The size of pool, and pool fire, formed depends on whether ignition occurs immediately. If ignition is delayed the radius of the pool from a 32 te wagon would be some 24 m and that for a 75 te wagon some 37 m. With immediate ignition, the pool radius in both cases would be 12 m. The pool radii for instantaneous releases would be similar.

A17.7.5 LPG events

For LPG, the scenarios are instantaneous releases of 20 and 40 te and continuous releases of 2 and 32 kg/s.

If the release is instantaneous and is ignited immediately, a fireball occurs. Otherwise, a flammable cloud forms. If this cloud is ignited, there is either a flash fire or a VCE.

If the release is continuous and is ignited immediately, a torch fire or a BLEVE occurs. Otherwise a flammable cloud forms. If this cloud is ignited, there is either a flash fire or a VCE. The flash fire may be accompanied by a torch fire or a BLEVE.

The report gives event trees for these scenarios.

A17.7.6 Chlorine and ammonia events

For chlorine and ammonia, the scenarios considered are as follows:

	Chlorine	*Ammonia*
Two-phase release from valve (kg/s)	1.3	2.1
Single phase release from puncture (kg/s)	45.1	33.5
Instantaneous release from catastrophic failure (te)	29	53

The development of these events is determined using the hazard models described.

A17.7.7 Marshalling yards

In addition to these en route events, the report also addresses releases occurring in marshalling yards. The two materials of interest in this regard are LPG and chlorine. The frequency estimates for these events for the two materials are given in Chapter 23.

The release scenarios considered are the same as for the en route case.

A17.8 Road Transport

The hazard of road transport of non-explosive materials is considered in Appendix 9 of the report.

An account has been given in Chapter 23 of the road transport environment in the United Kingdom. It includes data given in the ACDS report on tanker capacities and movements and on release frequencies and probabilities.

A17.8.1 Vehicles and movements

For the four hazardous materials studied, the road tanker capacities and movements are given in Table 23.6. The tanker capacities are for motor spirit 20–25 te, for LPG 15 te, for chlorine 17 te and for ammonia 15 te.

A17.8.2 Exposed population

The population exposed to an en route road accident considered in the report are the personnel of the vehicles involved, the other road users and the general off-road population.

The road transport situation is rather different from that of rail. In particular, it is necessary to take into account the wide variety of types of road and road usage.

Another basic difference is that the probability of other persons becoming involved in an incident is much higher for road than for rail.

For the density of the general population along the road the method is essentially similar to that used for rail transport.

The exposure of other road users to hazard from a road tanker is treated in terms of two zones, one for users behind the tanker and one for users on the other side of the road. For the former it is assumed that traffic backs up behind the tanker and that the section of the zone ahead of it is clear. In the second zone, on the other carriageway, the population density depends on whether the traffic stops or continues to move. It is assumed that the density in this zone is half that in the first zone.

The density of the road user population backed up behind the tanker is computed as follows. The traffic is assumed to consist of 10% heavy goods vehicles (HGVs). The length of road occupied by an HGV is taken as 20 m and that occupied by other vehicles as 4 m. There are assumed to be 1.5 persons/vehicle. This yields for motorways and for other roads population densities of 0.056 and 0.05 persons/m^2, respectively.

The full set of eight zones defined in the report comprises four on the same side of the road as the tanker and four on the other side. Zone a is one of standard population density, Zone b one of high density, Zone c a clear zone and Zone d the zone of road users behind the tanker. Zones h, g, f and e are, respectively, the corresponding zones on the other carriageway.

With regard to air infiltration into vehicles, work by M. Cooke (1988) has shown that for a car travelling at 40 miles/h the ram effect is sufficient to give one air change per minute and air ingress will be even greater if the ventilation fan is on. For a stationary car use of the ventilation fan will again give about one air change per minute. Even if the fan is off, the car is not expected to provide significant protection, the volume of the air space being small.

A17.8.3 Initiating events and event frequencies

The report considers two main types of initiating event. These are puncture of a tanker by collision and failure or maloperation of the tanker equipment.

The treatment given for the frequency of these events for each of the four substances and for the probability of ignition, immediate or delayed, of flammables is described in Chapter 23.

A17.8.4 Motor spirit events

For motor spirit, the scenarios considered are instantaneous releases of 4, 8 and 12 te and a continuous release of 25 kg/s (equivalent to a 100 mm hole). The tankers contain six compartments and the instantaneous releases correspond to spills from one, two or three of these.

A release of motor spirit, if ignited, results in a pool fire. The pool spread and fire model used is described in Section A17.4.

The pool areas obtained are

Spill	*Pool area* (m^2)	
	Immediate ignition	*Delayed ignition*
25 kg/s	314	908
4 te	707	1018
8 te	1385	1964
12 te	2124	3019

A17.8.5 LPG events

For LPG, the scenarios are an instantaneous release of 15 te and continuous releases of 2 and 32 kg/s.

If the release is instantaneous and is ignited immediately, a fireball occurs. Otherwise, a flammable cloud forms. If this cloud is ignited, there is either a flash fire or a VCE.

If the release is continuous and is ignited immediately, a torch fire or a BLEVE occurs. Otherwise a flammable cloud forms. If this cloud is ignited, there is either a flash fire or a VCE. The flash fire may be accompanied by a torch fire or a BLEVE. The report gives event trees for these scenarios.

A17.8.6 Chlorine and ammonia events

For chlorine and ammonia, the scenarios considered are as follows:

	Chlorine	*Ammonia*
Two-phase release from valve (kg/s)	1.3	2.1
Single phase release from puncture (kg/s)	45.1	33.5
Instantaneous release from catastrophic failure (te)	17.5	15

The development of these events is determined using the hazard models described.

A17.8.7 Lorry stopover points

In addition to these en route events, the report also addresses releases occurring at lorry stopover points. The three materials of interest in this regard are LPG, chlorine and ammonia. The frequency estimates for these events for the three materials are given in Chapter 23. The release scenarios considered are the same as for the en route case.

A17.9 Marine Transport: Ports

The treatment of marine transport in appendix 7 of the ACDS report is confined to the hazard at ports, which constitute fixed installations.

The study of ports was performed using the SAFETI code.

A17.9.1 Ports

There are in the United Kingdom some 42 ports with handling profiles exhibiting wide variety. The approach adopted was to study a set of three ports which had a representative set of major hazards. These ports were River Tees, the largest British chemical port complex; Felixstowe, a busy port with moderate hazardous trades; and Shoreham, a small port with petroleum product trades.

A17.9.2 Materials and movements

The principal hazardous materials and the movements of these materials through British ports are shown in Table A17.6.

A17.9.3 Exposed population and ignition sources

The model for the exposed population is that incorporated in the SAFETI code. The population is characterized in terms of the numbers of persons within 100 m grid squares. Separate distributions are used for night and day, the night-time figures being based on census data and the day-time ones on adjustments to these data. The density of ignition sources is also modelled using the grid square method, with values of ignition probability assigned on the basis of judgement.

A17.9.4 Initiating events and event frequencies

The report first considers the following types of marine event: (1) collision, (2) grounding, (3) striking and (4) impact. A collision occurs where two ships run into each other, a striking where a moored vessel is struck by a passing vessel and an impact where a vessel runs into a dock wall or jetty.

The starting point for the estimation of the frequency of these events at British ports was a study by the National Ports Council (1976), which was somewhat old and has known defects. The data were therefore re-analysed and supplemented by three additional data sets. The results of this analysis are given in Table A17.7(A).

The effects of these events were assessed separately for tankers and for gas carriers. For tankers the effects were taken to be (1) collision or striking below water, (2) collision or striking above water, (3) grounding damage or (4) impact damage. For each case a representative hole size was assigned.

For gas carriers all four marine events were assumed to have one of two effects: (1) cold leak through a hole or (2) cold rupture of the tank contents. For a cold leak the hole size was taken as that of the loading pipe connection, located at the bottom of a prismatic tank or at the mid-height of a spherical or cylindrical tank. For a cold rupture the release was taken as instantaneous from a pressurized tank or as occurring over 5 min from a refrigerated tank. It was assumed that 90% of the releases were leaks and 10% ruptures.

Four other events were also considered: (1) transfer spills, (2) tanker explosion, (3) gas carrier fires and (4) ammonium nitrate ship explosions.

The frequency of transfer spills was estimated from incidents reported to the HSE under NADOR in a 5.25 year period 1981–86. Transfer spills tend to be small and possibly, unreported. There were only eight spills reported, and just one for liquefied gas.

There are significant differences between cargos and transfer arrangements which will affect the frequency of transfer spills. Differences identified included (1) cargo

Table A17.6 *Hazardous cargos handled at British ports (after Advisory Committee on Dangerous Substances, 1991)*

A Overall

Material group	*Terminals*	*Visits* (ships/year)	*Amount per terminal* (te/year)	*Amount per movement* (te/ship)	*Total amount* (te/year)
Crude oil	17	1,957	9,244,347	80,291	157,153,891
Low flashpoint products	43	5,163	478,261	3,983	20,565,228
High flashpoint products	41	3,126	340,233	4,463	13,949,554
Flammable liquefied gas	26	2,388	374,180	4,008	9,674,268
Toxic liquefied gas	4	87	113,826	5,233	455,303
Low flash chemicals	21	1,244	105,689	1,771	2,205,975
High flash chemicals	23	1,399	119,689	1,945	2,739,746
Explosive chemicals	19	258	14,283	1,052	271,377
Total		15,662			207,015,342

B Liquefied gas

Liquefied gas	*Visits* (ships/year)	*Total amount* (te/year)
Ammonia	87	455,303
Butadiene	14	20,990
Butane	548	2,247,856
C_4 mix	227	236,151
Ethane	76	250,848
Ethylene	255	623,886
LPG[a]	555	2,339,388
Propane	414	3,470,246
Propylene	222	354,824
VCM	78	130,079
Total	2476	10,129,571

[a] LPG comprises propane–butane mixes in varying proportions.

Table 17.7 *Frequency of some marine accidents at British ports (after Advisory Committee on Dangerous Substances, 1991)*

A Accidents by port type

	Collisions (per encounter)	*Grounding* (per km)	*Striking* (per passing)	*Impact* (per visit)
Open sea port	5.0×10^{-4}	6.5×10^{-5}	4.0×10^{-6}	2.2×10^{3}
Wide estuary	4.0×10^{-5}	8.0×10^{-6}	4.0×10^{-6}	2.2×10^{3}
Wide river	1.2×10^{-4}	1.6×10^{-5}	9.0×10^{-6}	2.1×10^{3}
Narrow river	5.0×10^{-4}	6.5×10^{-5}	4.2×10^{-5}	6.5×10^{3}

B Accidents by cargo group

	Transfer accident (per cargo transferred)	*Explosion* (per visit)
Crude oil	1.9×10^{-4}	1.3×10^{-5}
Low flash products	1.8×10^{-4}	3.5×10^{-6}
High flash products	1.8×10^{-4}	1.5×10^{-6}
Flammable liquefied gas	7.6×10^{-5}	–
Toxic liquefied gas	7.6×10^{-5}	0
Low flash chemicals	1.5×10^{-4}	1.3×10^{-5}
High flash chemicals	1.5×10^{-4}	0
Ammonium nitrate	0	7.0×10^{-6}

(liquid, pressurized liquefied gas or refrigerated liquefied gas), (2) transfer equipment (articulated hard arm or flexible hose), (3) proportion of cargos unloaded, (4) use of vapour recovery, (5) use of ranging alarms, (6) emergency shut-down system (none, basic or advanced), (7) quick release coupling (none, pre-1987 or post-1987) and (8) environment (berth tidal or non-tidal, number of passing vessels).

The various transfer spills were condensed into four: (1) 3 min full bore (LG only), (2) 5 min full bore (liquid cargos only), (3) 15 min full bore and (4) 10 min at 10% full bore.

Event trees were constructed to assist in estimating the proportion of each of these different outcomes. The branches in the event trees were determined by the following three factors (1) immediate operator reaction (within 1 min), (2) operation of BSD within 10 min and (3) effectiveness of BSD when operated.

The results of this work are the transfer spill frequencies shown in Table A17.7(B).

Tanker explosion frequencies were obtained from analysis of cases world-wide in Lloyds Casualty Returns for the period 1977–86. Table A17.7(B) shows the results.

The frequency of gas carrier fires was obtained from the study by Blything and Edmondson (1984 SRD R292). The data were processed to give incident rates per visit and per kilometre of approach.

It was estimated that there have been nearly 100 fire incidents but without any release of a cargo. Applying the statistics for the case of no event over a period of time, the estimate obtained for the probability of cargo release given a fire was 0.007. It was then assumed that 90% of such cases are hot leaks and 10% hot ruptures. Only the latter was considered further, the former being treated as leaks through safety valves which are consumed by the fire on the vessel.

For ammonium nitrate (AN) explosions the use of historical data was eschewed, since such incidents occurred many years ago and involved organic-coated material which is no longer used. Instead use was made of fault trees to predict the explosion frequency, the main path being a fire, probably from the engine room, entering a hold and melting part of the AN. Explosion could then be initiated by confinement, organic contamination or impact shock. The estimated frequency of AN ship explosions so obtained is 6.2×10^{-8} per cargo.

A17.9.5 Releases of flammable liquefied gas

Releases of flammable liquefied gas were modelled using the emission and dispersion models in SAFETI. The detailed treatment of the emission scenarios for cold releases, namely cold leaks from and cold rupture of pressurized and refrigerated tanks, is described in the report. The dispersion of the vapour was then obtained using the dense gas dispersion model.

The ignition model in the code is then used to determine the proportion of cases in which the cloud is ignited. The proportion of ignitions resulting in a VCE is taken as 10%, the other 90% as giving a flash fire.

Hot rupture of a pressurized tank is assumed to give a fireball. The size of tank is typically several hundred tonnes and the size of the resultant fireball is well outside the range for which correlations have been validated.

Hot rupture of a refrigerated tank was initially also assumed to give a fireball, but this outcome is uncertain. A pool fire may well be more likely. Modelling of these two alternatives for this case indicated that they present comparable hazards.

A17.9.6 Releases of toxic liquefied gas

Releases of liquefied ammonia were modelled using the emission and dispersion models in SAFETI.

A17.9.7 Explosions of flammable liquid

For flammable liquid explosions modelling of representative events in respect of overpressure and fragments indicated that they are not in general significant beyond the vessel.

Such explosions do, however, cause casualties amongst the crew. From analysis of tanker losses in port in the period 1977–86 the following estimates were derived:

Proportion of crew killed	*Probability given cargo explosion*
0.15	0.37
0.40	0.11
0.65	0.04
1.0	0.04

A17.9.8 Ammonium nitrate explosions

Ammonium nitrate explosions are modelled using the TNT model with an appropriate value for the TNT equivalent of AN. For bagged AN this was taken as 13% of the shipment mass and for bulk AN as 33%. These values include allowance for the TNT equivalent of AN, the probable mass aboard when the explosion occurs and the efficiency of explosion for the different types of storage.

A17.9.9 Representative ports

The report gives the results of the detailed studies for the three representative ports of River Tees, Felixstowe and Shoreham.

A17.9.10 Extension to all ports

The risk results obtained for the three representative ports were applied using a ‘simplified method’, details of which are given in the report, to obtain an estimate of the national societal risk.

A17.10 Transport of Explosives

The hazard from the transport of explosives by rail and road is considered in Appendix 10 of the report.

A17.10.1 Categorization of explosives

The hazards presented by explosives include blast, fragments and fireball. The hazard which predominates in a particular case depends on the class of explosive.

The classification generally used in transport is the UN scheme, described in Chapter 23. The classes of explosive in this scheme which are of prime interest here are

HD1.1	Mass explosion hazard;
HD1.2	Projection hazard;
HD1.3	Fire hazard;
HD1.4	No significant hazard.

For the purpose of hazard assessment, the ACDS found it necessary to develop a categorization more adapted to this purpose, which reflects particularly the heat sensitivity of the substance or articles:

UN class	*ACDS category*	
	M	Heat sensitive substances in flammable packaging
HD1.1	N	Heat sensitive articles – not readily ignitable
	P	Heat insensitive substances
HD1.2	Q	Heat sensitive articles
HD1.3	R	Heat sensitive substances in flammable packaging
	T	Heat sensitive articles and substances in non-flammable packaging
HD1.4	W	Heat sensitive articles which present no great hazard

A17.10.2 Limits on loads

In the United Kingdom there are limits set to the load of explosive which can be carried. These are 16 te for a lorry and 20 te for a rail wagon, with a further limit of 40 te for a train.

A17.10.3 Rail transport of explosives: explosives and movements

The explosives moved in rail transport are predominantly (>97%) military explosives. In the year 1988/89 BR data showed that there were 8132 movements of wagons containing explosives. The average explosives train journey is 320 km and the explosives movements are therefore 2.6×10^6 wagon km/year.

A special investigation was made of the composition of this traffic, which was found to be by Hazard Division as follows: HD1.1 21%; HD1.2 12%; HD1.3 10% and HD1.4 44%. The explosives traffic was also analysed by the HSE categorization scheme, which yielded by proportion of wagons the following dominant categories: N 10%; P 11%; Q 12%; T 10%; W 44%; N/T 3% and Q/W 4%. Some 27% of explosives wagons contained HD1.1 explosives, while 44% contained only HD1.4.

An analysis was also conducted to obtain the average values of the NEQ, effectively TNT equivalent, of the loads.

A17.10.4 Rail transport of explosives: exposed population

The population exposed to the rail transport of explosives was determined in the study using a method essentially similar to that used for the four non-explosive substances.

In the event, the assessment showed that for rail the risk is predominantly to the off-site population.

A17.10.5 Rail transport of explosives: initiating events and event frequencies

The main mechanisms identified in the report for the initiation of explosives are (1) fire, (2) impact and (3) unsafe explosives.

An analysis was made for rail and road transport of data from various sources including the minutes of the ESTC of the MoD, the annual reports of HM Inspector of Explosives and the SRD explosives database EIDAS. There was for the United Kingdom over a 40 year period only one accident involving fatality, that at Peterborough in 1989 (HSE, 1990c). However, for both rail and road there were a number of dangerous occurrences, listed in Annex 2 of Appendix 10.

The report discusses in detail the methods by which it obtains its estimates of the explosive events in both forms of transport.

For rail transport it gives the following frequencies:

Initiating mechanism	*Frequency* (events/wagon km)
Unsafe explosives	1×10^{-9}
Fire	6×10^{-10}
Impact	1×10^{-10}

The frequencies of events from unsafe explosives and from fire are thus assessed as broadly comparable, that assessed for events from impact being much lower.

A17.10.6 Rail transport of explosives: explosions en route

The explosion event depends, as stated earlier, on the class of explosive carried, being for HD1.1 a mass explosion, for HD1.2 fragments and for HD1.3 a fireball. The models described in Section A17.4 were applied using the hazard impact method given in that section.

A17.10.7 Rail transport of explosives: explosions in marshalling yards

The study identified one marshalling yard which handled some 50% of explosives traffic and in which explosives were present almost continuously. An outline assessment was made, although no formal estimates of individual or societal risk were produced.

Application of the hazard model for the different classes of explosive showed that none of the events had a range to 10% lethality of more than 50 m. The population at this yard was beyond 110 m.

Analysis resulted in the following estimates for the frequency of initiation of an explosive load in a marshalling yard

Initiating mechanism	*Frequency* (events/year)
Unsafe explosives	1×10^{-3}
Fire	2×10^{-4}
Impact	2×10^{-4}

A17.10.8 Road transport of explosives: explosives and movements

An investigation was made of the composition of the road explosive shipments broadly similar to that made for rail. It was found to be by Hazard Division as follows: HD1.1 94%; HD1.2 2%; HD1.3 40%. The explosives traffic was also analysed using the ACSD categorization scheme, which yielded by mileage covered the following categories: M 51%; N 23%; P 20%; Q 2%; R 3%; T 1%.

An analysis was also conducted to obtain the average values of the NEQ of the loads. The loads were classified into three bands with the load being distributed according to the following probabilities

Band	*Mean NEQ* (kg)	*Proportion of total mileage* (%)
1	316	18
2	1,778	68
3	14,125	14

A17.10.9 Road transport of explosives: exposed population

The population exposed to the road transport of explosives was determined in the study using a method essentially similar to that used for the four non-explosive substances.

In the event, the assessment showed that for road the risk is predominantly to the road users.

A17.10.10 Road transport of explosives: initiating events and event frequencies

The initiating events in road transport are the same as those for rail transport. The analysis made to obtain the frequency of the road events has been described above. The detailed methods are given in the report.

For road transport it gives the following frequencies:

Initiating mechanism	*Frequency* (events/vehicle km)
Unsafe explosives	1×10^{-9}
Fire	2×10^{-9}
Impact	2×10^{-10}

The figures are somewhat similar to those for rail transport, the frequencies of events from unsafe explosives and from fire being assessed as broadly comparable, that assessed for events from impact being much lower.

A17.10.11 Road transport of explosives: explosions en route

The explosion event was modelled in a manner essentially similar to that used for rail transport. The models described in Section A17.4 appropriate to the class of explosive – HD1.1, HD1.2 or HD1.3 – were applied using the hazard impact method given in that section.

A17.10.12 Road transport of explosives: explosions at lorry stopover points

For explosives the situation at lorry stopover points is quite different from that at marshalling yards. Such points are always on premises licensed for the purpose. Lorries also stop briefly en route, but such stops are brief and are always attended. This risk was not pursued.

A17.11 Risk Criteria

The ACDS report gives in Appendix 6 a review of the principles underlying the setting of risk criteria and of the application of these to individual and societal risk.

The basic principle is that the risks should be as low as reasonably practicable (ALARP).

A17.11.1 Individual risk

With regard to individual risk to members of the public, the report refers to proposals made by the HSE. At the Hinkley Point Inquiry the HSE proposed that a fatality risk of 10^3/year is 'intolerable', though subsequent discussion suggested a lower level of intolerability. The HSE has also proposed a fatality risk of 10^{-6}/year as 'broadly acceptable'. The report adopts these criteria.

A17.11.2 Societal risk

In respect of societal risk, the ACDS criteria are formulated in terms of FN curves. A distinction is made between an FN curve for risk at national level and one for risk at local level. Both types of risk occur in the study, the en route risks of rail, road and explosives transport being treated mainly as national and the risks at fixed sites such as ports, marshalling yards, lorry stopover points and unloading points as local.

The basic principle is illustrated in Figure 9.39, which shows an FN criterion plot for a local risk. The FN space is divided into four parts by three lines. The upper line is the tolerability line. Risks above this line are regarded as intolerable. The middle line is the scrutiny line. Risks between this line and the tolerability line may be unjustifiable and require further study. The bottom line is the negligible risk line. Risks below this line are regarded as negligible. Those between the negligible risk line and the scrutiny line should be reduced applying the ALARP principle.

For the local risk criterion FN plot the ACDS proceeds as follows. The reference point is the risks assessed at Canvey. These risks were regarded as on the borderline of tolerability. The values used by the ACDS for these risks are one third those predicted in the Second *Canvey Report* (HSE 1981a). This Canvey FN curve is then used as a guide both to the setting of the absolute value of the tolerability line and to its slope. This is illustrated in Figure A17.3.

The negligible risk line for the local FN plot is set three decades below the tolerability line. The arguments for this are based essentially on examination of the implications of setting it either two or four decades below. If the line were two decades down, the expectation value would be six fatalities per 1000 years. Applying a value of a life of £0.5 million gives a potential expenditure of £3000 per annum, which might justify a QRA done every 10 years. It is argued that such a risk could hardly be regarded as negligible. On the other hand, if the negligible risk line were to be set four decades below the tolerability line, this would justify a potential expenditure of £30 per annum or £300 every 10 years. On the basis of the cost of staff time this would barely permit even a cursory discussion, which suggests that this setting of the line is well into the negligible risk region. The slope of the tolerability line, and of the other lines, is –1, again reflecting the assessed risk at Canvey.

The treatment in the report for the national risk criterion FN plot is less firm. A tentative scrutiny line is developed for ports which is derived not from any argument based on direct combination of the number of ports and of the local criteria but rather on the implication of transferring trade from any port where the risks are already at the tolerability limit. This line is entered on the FN plot for national societal risk for ports and also on other national societal risk plots as shown in the following paragraphs.

A17.11.3 Value of a life

As already mentioned, the report refers to the figure of £0.5 million for the avoidance of a statistical fatality, or the value of a life, used by the Department of Transport. It gives in appendix 7 on ports a discussion of cost benefit analysis of proposed remedial measures in which a factor of 4 is applied to this figure, yielding a value of a life of £2 million (1991 value) to allow for 'gross disproportion' and uses this latter in the subsequent analysis.

A17.12 Assessed Risks

The assessed risks quoted in the study are now described. The report is careful to quote confidence bounds and to

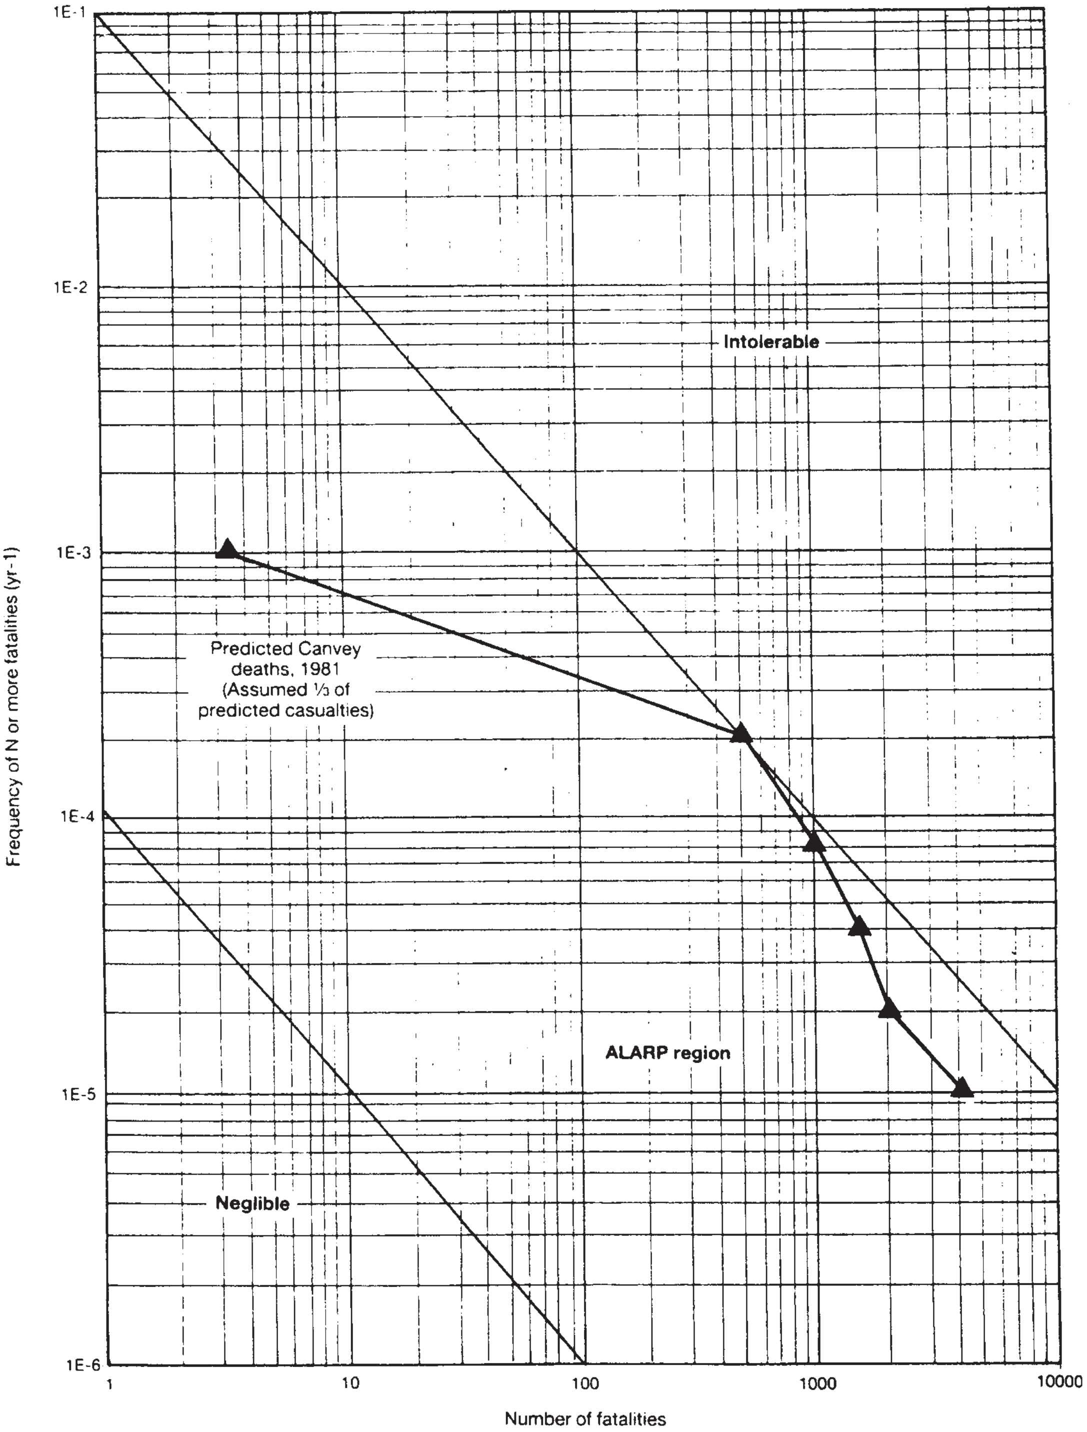

Figure A17.3 *FN curve risk criterion proposed by the ACDS for an identifiable community, E–n = 10^{-n} (Advisory Committee on Dangerous Substances, 1991) (Courtesy of HM Stationery Office). Five concentrations are calculated at which the probabilities of fatal injury are close to 1.0 (concentrations C_1, C_2) and 0.9, 0.5 and 0.1 (three concentrations C_3). For each concentration there is a corresponding probability of escape indoors, the values used being 0 for C_1, 0.2 for C_2 and 0.8 for C_3*

Figure A17.6 *Continued*

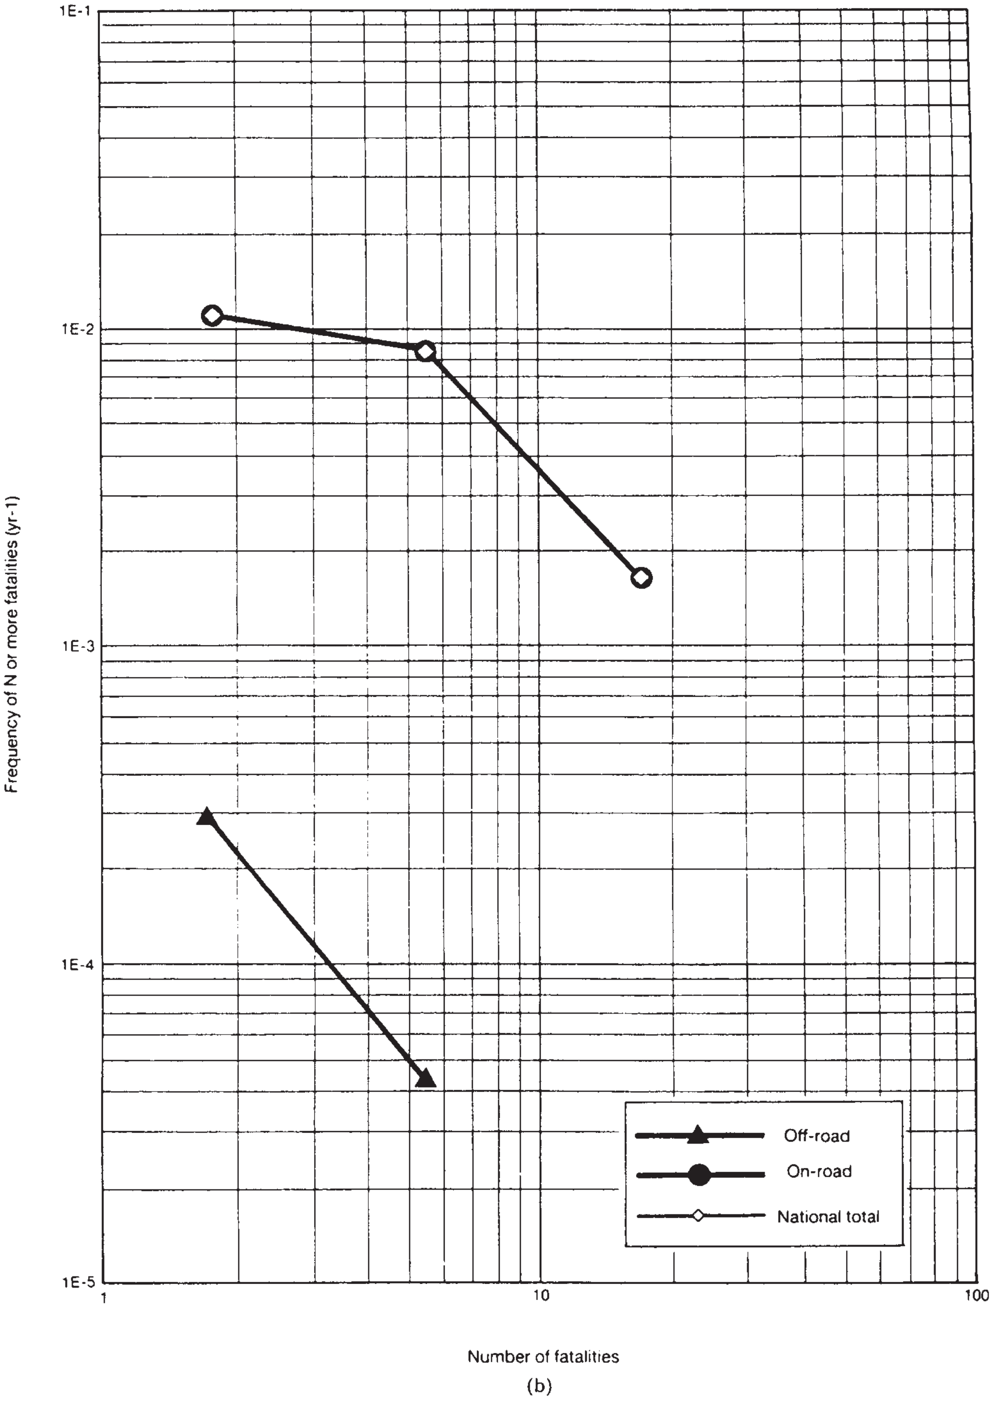

Figure A17.6 *FN curves for national societal risks from rail and road transport of explosives (Advisory Committee on Dangerous Substances, 1991): (a) rail transport and (b) road transport, E–n = 10^{-n} (Courtesy of HM Stationery Office)* note uncertainties in, and qualifications to, the figures given. The account given here is in outline only.

A17.12.1 Rail and road transport

The assessed risks of rail and road transport for the four non-explosive materials are presented as individual risks, as societal risks in the form of FN curves and as expectation values.

The individual risk to the public for rail transport of the four materials is assessed as negligible. For example, for a person living 50 m from the track the fatality risk from chlorine transport is predicted to be 2.4×10^{-7}/year. For road transport, the situation is rather more complex in that there may be certain locations such as a sharp corner which have a higher than average risk. But in general the risk is assessed as negligible and as only a small fraction of the overall risk faced by road users.

The national societal risks assessed for the transport of the four materials, and for the combination of these, are shown in Figures A17.4(a) and (b) for rail and road, respectively. For rail transport the predominant risks are from motor spirit and ammonia, for road transport from motor spirit and LPG. For both modes the risk lies between the tolerability and negligible risk lines.

The expectation values of the annual number of fatalities for the rail transport of motor spirit and ammonia are 0.074/year and 0.3/year and those for the road transport of motor spirit and LPG are 1.1/year and 0.8/year, respectively.

The report gives in Appendix 11 a comparison of the relative risks from rail and road transport. It makes the point that the choice of mode is not unrestricted. For example, motor spirit deliveries must at some stage be by road. A comparison of the rail and road risks shown in Figures A17.4(a) and (b) suggests that the risks of road transport are higher, but these graphs are for risks from actual traffic flows. Fair comparison needs to be based on a pattern of shipments which is the same for both modes. The report gives a detailed discussion but the overall conclusion is that the assessment made provides little support for a general preference for either mode on the grounds of safety.

A17.12.2 Ports

As far as regards ports, the study of the three ports found that in some limited areas near the ports individual risk was such that on the basis of the risk criteria adopted advice would be against new housing development.

The assessed societal risks are shown in Figure A17.5(a) and (b). The former shows the local societal risk for one of the ports, Felixstowe, obtained from the individual assessment for that port, and the latter the national societal risk for British ports, obtained from the simplified method described above. At none of the three ports was the local societal risk within the scrutiny zone. The national societal risk is also outside that zone.

A17.12.3 Transport of explosives

Turning to the risk from the transport of explosives, individual risk from en route transport by rail or road was not judged significant, but there was one marshalling yard where it might be.

The national societal risks from rail and road transport of explosives are shown in Figures A17.6(a) and (b), respectively. The risks from road transport are higher by an order of magnitude. This is accounted for only in part by the greater volume moved; the proximity of other road users is also a factor. As Figure A17.6 shows, for explosives the principal contributor to the assessed societal risks in rail transport is the off-site population, whereas for road transport it is the road user population. For rail the fraction of the total risk contributed by the rail users is negligible, while for road the fraction contributed by the off-site population is 2–3%. For both modes the risk lies between the tolerability and negligible risk lines. The report indicates that further scrutiny would be appropriate.

A17.13 Risk Evaluation and Remedial Measures

The ACDS report gives an assessment of individual and of local and national societal risks, identifies certain activities or situations where the risks may need to be reduced or at any rate should be subject to further scrutiny and in Appendices 7, 10 and 12 makes proposals for a number of remedial measures.

One measure of general applicability is adherence to, and enforcement of, good working practice.

There are also various measures appropriate to the particular activity. For rail, it is suggested that the design and construction of tanker wagons for motor spirit and for ammonia, the improvement of communication by provision of radio telephones and the training of train drivers should receive attention.

For road, measures suggested relate to the design and construction of road tankers, use of designated routes, movement by night, provision of improved communication and availability of information in a chemical emergency and the training of drivers. Technical measures referred to for tankers are devices to monitor tyre pressure and so reduce the risk of a tyre fire; additives for middle distillates to reduce the risks from static electricity during switch loading and cut-off devices to prevent engine overrun leading to possible ignition of vapour from spills following a tanker puncture. There may be scope for reduction of risk by the use of designated routes. Communications could be improved by provision of radio telephones. Information on the characteristics and emergency handling of chemicals carried should be available from chemical emergency information centres 24 hours a day.

For ports, the proposals made in the report include measures related to hard arm loading equipment and ESD systems, communications within the port, control of pleasure vessels and land use planning.

While many of these proposals might be made without benefit of a hazard assessment, the study provides guidance on priority areas. It identifies a number of features as meriting further scrutiny. These include the dominant contribution of motor spirit and ammonia to the en route national societal risks of rail transport and of motor spirit and LPG to those of road transport; the existence of individual risk with land use planning implications within 100 m of lorry stopover points and the national societal risk for road transport of explosives.

At least as important as the assessed levels of risk is the improved understanding of the hazards involved. An example is the relative contributions to the national societal risk in the transport of explosives of the off-site and rail or road user populations.

Also of value are the negative results from the study. For the four non-explosive materials the report states that the risks from marshalling yards are not such as to inhibit further housing development in the zone where houses currently exist.

A17.14 Notation

a–d	constants
A	area (m^2)
C	concentration
D	population density (persons/m^2)
I	thermal radiation (kW/m^2)
N	number of fatalities
p^o	peak side-on overpressure
$P_{f\|id}$	probability of fatal injury given that a person is indoors and within the cloud
P_{id}	probability that a person is indoors
P_{od} A	probability that a person is outdoors
t	exposure time
Y	probit

Equation A17.5.2

p^o	peak side-on overpressure (psi)

Equation A17.5.6

C	concentration of ammonia (ppm)
t	time (s)

Offshore Process Safety

Contents

Any account of loss prevention needs to include some mention of offshore oil and gas activities, even if this is necessarily brief. There is a continuous interaction between developments onshore and offshore. The treatment given here is confined to an outline of offshore safety activities.

Offshore installations operate in a difficult and often hostile environment. The problems, not only of structures but also of processing, are challenging. The solution of these problems often involves technological innovation. The significance of this for safety and loss prevention is clear.

The report into the Piper Alpha disaster (Cullen, 1990), known as the *Cullen Report*, provides a wealth of detail both on the design and operation of an actual platform, albeit one of the older ones, in the North Sea and on the impact on it of a major accident event.

Accounts of offshore oil and gas are given in *Offshore Oil Technology* by Ranney (1979), *Onshore Impacts of Offshore Oil* by Cairns and Rogers (1981), *Introduction to Petroleum Development* by Skinner (1982), *Technological Guidelines for Offshore Oil and Gas Development* by Gilbert (1983), *Gas Production Operations* by Begg (1984), *Behaviour of Offshore Structures* by Battjes (1985) and *Safety in the Offshore Petroleum Industry* by Barrett, Howells and Hindley (1987) and by R.J.S. Harris (1978), Holmes and Mead (1978), Timar (1978), Shyvers (1981) and Waldie (1986).

The series of booklets by BP Petroleum Development Ltd (1990a–g) constitutes a useful starting point.

Much useful information is also given in *Offshore Installations*: *Guidance on Design, Construction and Certification* by the HSE (1990b), also called the *HSE Onshore Design Guide*.

Selected references on offshore safety are given in Table A18.1.

A18.1 North Sea Offshore Regulatory Administration

An outline of the legislation governing oil and gas activities in the UK sector of the North Sea has been given in Lees Edition 3, Chapter 3, with a summary of the principal legislation given in Table A18.2.

Two principal elements of the administration are the systems of internal control and of risk assessment. The *Guidelines for the Licencee's Internal Control 1979* describe in effect an SMS. The *Regulations Related to the Licencee's Internal Control 1985* make this a regulatory requirement.

With regard to risk assessment, the *Regulations Concerning Safety Related to Production and Installation 1976* contained a requirement that if the living quarters were to be located on a platform where drilling, production or processing of petroleum was taking place, a risk evaluation should be carried out. At this date the evaluation was largely qualitative. The move to a more quantitative approach came with the *Guidelines for Safety Evaluation of Platform Conceptual Design 1981*. These had as a central feature, the provision of a sheltered area, required the conduct of a concept safety evaluation (CSE) and specified numerical acceptance criteria.

The Guidelines defined a design accidental event as one that does not violate any of the following three criteria:

- at least one escape way from central positions which may be subjected to an accident, shall normally be intact for at least an hour during a design accidental event;

- the shelter area shall be intact during a calculated accidental event until safe evacuation is possible;
- depending on the platform type, function and location, when exposed to the design accidental event, the main support structure must maintain its load carrying capacity for a specified time.

The categories of potential accident event to be evaluated were specified as

(1) blowouts,
(2) fire,
(3) explosion and similar incidents,
(4) falling objects,
(5) ship and helicopter collisions,
(6) earthquakes,
(7) other possible relevant types of accident,
(8) extreme weather conditions and
(9) relevant combinations of these accidents.

The Guidelines gave explicit numerical acceptability criteria. In practical terms, it may be considered necessary to exclude the most improbable accidental events from the analysis. However, the total probability of occurrence of each type of excluded situation should not by best available estimate exceed 1 CT^{4} per year for any of the main functions specified. This estimate is meant to indicate the order of magnitude to aim for, as detailed calculations of probabilities in many cases will be impossible due to lack of relevant data.

Risk assessment is now the subject of the *Regulations Relating to the Implementation and Use of Risk Assessment in the Petroleum Activities 1990.* Ognedal emphasized that the Norwegian attitude is flexible in its approach to risk assessment and tries to avoid its degenerating into a 'numbers game'.

The *Cullen Report* recommended far-reaching changes in the regulatory administration in the British sector of the North Sea. The recommendations flow from the evidence given on the Piper Alpha disaster and on the regulatory administration up to that date. The administration envisaged is one of goal-setting rather than prescriptive regulations and of the use of QRA to demonstrate compliance. The report also recommended that an operator should submit a safety case and that this should be given structure by a requirement to demonstrate by QRA the integrity of a temporary safe refuge (TSR). Another major recommendation is that the operator demonstrate, as part of the safety case, an appropriate Safety management system (SMS). A further account of the report's recommendations in relation to the evidence on the Piper Alpha disaster is given in Appendix 19.

The recommendations of the *Cullen Report* were accepted in toto by the government and the new administration with the HSE as the regulatory body was put in place in 1991. Initial legislation under this administration includes the *Offshore Safety Act 1992* and the *Offshore Installations (Safety Case) Regulations 1992*. Development of the new administration has been described by Barrell (1992a,b).

A18.2 Gulf of Mexico Offshore Regulatory Administration

The offshore petroleum industry began in the US Gulf of Mexico in the 1950s. The Coast Guard was the original regulatory agency, but the responsibility for offshore safety was eventually transferred to the Minerals Management Service (MMS). The safety regulations are found in the *UIS Code of Federal Regulations, Title 250.*

MMS directly references many of the American Petroleum standards and recommended practice documents. The API 14 series, contain standards for subsurface safety valves, platform safety systems, piping systems, electrical systems, and fire safety systems. The API t series recommended practices for offshore staff training is also codified by the MMS.

API 14C, the recommended Practice for analysis, design and installation of basic surface safety systems on offshore production platforms was originally promulgated in 1972. API 14C embodies two very important process safety concepts;

- Every identifiable failure mode shall require two functionally independent safeguards.
- Recommended safeguards for each type of offshore process unit (pressure vessel, pump, heater, etc) were developed using a generic failure mode and effects analysis.

The documentation showing the results of a 14C approach are presented in a Safety Analysis and Functional Evaluation diagram, known as a SAFE chart. The SAFE chart is a special type of cause and effect diagram.

A18.3 Offshore Process Safety Management

In the 1990s, MMS requested voluntary adherence to the API 75 and API 14G recommended practice documents, which present process safety concepts to the offshore environment. These standards are very similar to the OSHA process safety management regulation, containing virtually identical wording in many sections.

A18.4 Offshore Safety Management

An offshore platform has both marine and process characteristics. It shares with marine vessels the hazards of severe weather and of collision and *in extremis* those of escape to the sea. At the same time it contains high pressure plant processing oil and gas. The platform is also a self-contained community with its own power plant, accommodation and other facilities. The senior manager on the platform is required in large part to combine the skills of a ship's captain with those of a refinery manager and to exercise command and control in an emergency.

A18.5 Inherently Safer Offshore Design

The processing of hydrocarbons is the *raison d'etre* of an offshore platform. This clearly sets certain limitations on the practice of inherently safer design. Nevertheless, this design principle is just as applicable offshore.

Three examples will suffice. One is reduction in the oil inventory in the production separators. The separators constitute a major oil inventory on the platform and it was the separators that fed the oil pool fire on Piper Alpha. Separators are now in use which have much reduced inventories. It may be noted in passing that evidence on the hydrocarbon inventory on Piper Alpha was given to the Inquiry by Clark (1989).

A second example is adoption of a layout that minimizes the possibility of an oil pool forming near a gas riser.

A third example concerns the potential for a jet flame from a gas riser to impinge on the accommodation. Following Piper Alpha, Shell reviewed their platforms to establish whether in each case this was a possibility (Chamberlain, 1989). In those cases where it was, action was taken.

A18.5.1 Friendly plant

Closely related is the design of plant that is friendly to the process operator. In oil and gas extraction there are strong pressures to maintain production. In these circumstances, it is highly desirable that there be fallback states of plant operation to which the operator can resort, without facing the all-or-nothing choice of continuing normal production or effecting total shut-down.

A case in point is the confidence that the operator has that shutting down the gas plant will not lead to loss of power on the main generators. Evidence at the *Piper Alpha Inquiry* appeared to indicate that in some systems fuel changeover on the generators, from gas to diesel, could not be fully relied on. If this situation exists, it puts a greater pressure on the operator to keep going.

A18.5.2 Plant layout

Offshore production platforms carry large amounts of equipment held in a small space. Space and weight are both at a premium, since they are difficult and expensive to provide. Spacing between equipment in a module has to be less generous than in onshore plants. Where a 15 m distance is widely used in the latter, the distance offshore is often half that. It is also necessary to ensure that the layout is such that the centre of gravity of the total mass of equipment is at the centre of the supporting structure. CAD packages for plant layout provide a powerful tool for achieving a layout that meets this requirement.

The decks of the platform are divided into modules. The modules are separated by fire walls which inevitably reduce the ventilation.

Layout design seeks to separate sources of hazard from vulnerable targets. The application of this principle is seen on many platforms by the separation of the accommodation from the wellhead.

A18.5.3 Platform systems

There are a number of basic systems that are critical for safe operation of the platform. The account given here of these systems is limited to a brief overview. It is convenient to cast it as a description of the systems on Piper Alpha. The *Cullen Report* gives a detailed description of these systems and of their behaviour on the night of the disaster.

Electrical power systems

The first of the systems is the electrical power supply system. Basic power is supplied by a pair of main turbine-driven generators with dual fuel firing, gas being the normal fuel with diesel fuel as standby. As backup, there is an emergency generator, turbine-driven and diesel fuelled. Changeover of fuel on the main generator and start up of the emergency generator are automatic. Drilling is served by a separate power supply from a diesel-driven generator with its own emergency generators.

The emergency generator for the main supply is designed to provide supply to critical services, which include HVAC, instrumentation and valves, and emergency lighting. Further backup is provided by an uninterruptible power supply (UPS) drawn from batteries designed to provide power during the momentary interruption while the emergency generator starts up and, if necessary, for a period in the event of total failure of the main supply.

Electrical systems for offshore production platforms are the subject of API RP 14F: 1991.

Fire protection system

The fire protection system comprises a number of complementary elements. These are

- hazardous area classification,
- fire walls,
- fire and gas detection system,
- fire water deluge system,
- fire pumps,
- foam system,
- Halon or clean agent systems and
- fire fighting arrangements.

Fire prevention and control on offshore production platforms is covered in API RP 14G: 1986.

The first line of defense against fire is the use of hazardous area classification to reduce the risk of ignition of any flammable leak that may occur. This was formerly covered by API RP 500B: 1973, specific to offshore, which is now replaced by the general onshore and offshore code RP 500: 1991.

The traditional form of active fire protection is the water deluge system. This is covered by the NFPA Fire codes, *Construction and Use Regulations 1974* and the associated guidance in the *Offshore Design Guide*. The plant is divided into reference areas with a specified quantity of water to be delivered over each area. In order to limit the size of the reference areas use is made of firewalls. There are firewalls between the main production modules, namely the wellhead, separation and gas compression modules. These provide basic passive fire protection. They are not necessarily designed as blast walls.

There is an extensive fire and gas (F&G) detection system, with sensors in the main production modules and elsewhere, utilizing both combustible gas detectors and fire detectors.

A fixed water deluge system with distribution throughout the main modules and at the risers furnishes a basic level of active fire protection. Water for the deluge system is drawn from the sea by fire pumps operating off the main power supply but with diesel-driven pumps as standby.

At locations where an oil pool fire may occur, such as the production separators, foam injection is provided.

Certain closed volumes may be provided with a halon total flooding system. Enclosures which may be protected in this way include the centrifugal compressor enclosures, the generator area, the electrical switchgear room and the control room. Where, as in the latter case, operators may be present, a non-toxic agent is used and there is prior alarm. These fixed systems are supplemented by the fire fighting teams.

As just indicated, the traditional means of fire protection has been passive protection by firewalls and active protection by a uniform water deluge. Alternative approaches have tended to be inhibited by the need to comply with the two separate sets of regulations covering fire, one requiring passive and the other active fire protection measures.

In addition to the trade-off between passive and active fire protection, there may also be a trade-off between ventilation and active fire protection. If a module is well ventilated, gas from a leak is less likely to accumulate in the first place.

A plea for greater flexibility was made to the *Piper Alpha Inquiry* by Brandie (1989b), who advocated a scenario-based approach in which specific fire hazards are identified and water deluge arrangements directed more specifically to these scenarios. The *Cullen Report* recommended this approach within the context of *Safety Case*.

There are a number of issues related to fire protection. One is the availability of standard fire tests for hydrocarbon, as opposed to building, fires, such tests being needed for design of fire walls. Another is the use of passive fire protection on risers, which might involve a risk of corrosion beneath the lagging.

Another long-standing issue, which relates to active fire protection, is the availability of the fire pumps.

There is generally a strong argument for the use of passive fire protection in that once installed it appears less subject to human failings. The matter is not, however, straightforward. Thus, for example, in some applications corrosion may occur under fireproofing, which may both promote the corrosion and conceal it.

There is now considerable activity in the investigation of fire events on platforms, covering oil pool fires and jet flames; impingement of flames on vulnerable targets such as risers and passive protection of these targets. Further details are given in Section A18.7.

A18.5.4 Emergency shut-down system

The platform is provided with an emergency shut-down (ESD) system, the main functions of which are (1) to shut down the flow from the reservoir, (2) to shut off the flow through the pipelines entering and leaving the platform, (3) to shut down the main items of equipment and (4) to initiate blowdown of the inventories to flare. There are various levels of ESD, some involving only individual items of equipment and others a full platform ESD, or PESD. Physically, PESD may be activated from the control room or from any of a number of emergency pushbuttons around the platform.

As important as the hardware are the procedures that govern operation of the PESD system. It bears emphasis that the protection apparently afforded can be negated if there are cultural, organizational or human factors which inhibit initiation of the system in a real emergency.

A18.5.5 Evacuation, escape and rescue system

The evacuation, escape and rescue (EER) system is built around the three main means of leaving the platform, which are (1) helicopter, (2) lifeboat and (3) liferaft. The emergency procedure is for personnel to collect at designated muster points. In the vast majority of cases evacuation is by helicopter, personnel being summoned to the helideck from their muster points. There are a number of reasons, however, why evacuation by helicopter may be impractical. They include high winds and smoke from the platform, which can prevent landing. Another is the time taken to reach the platform. A helicopter already in or near the field may arrive relatively quickly but in many locations it takes about an hour for a helicopter to travel from an onshore base.

If helicopter evacuation is not practical, the other main means of getting off the platform is by lifeboat. The use of lifeboats is also subject to limitations. Lifeboats may sometimes be difficult to reach and have limitations in high seas. Even if the conditions do not actually prevent use, they may increase the risk of injuries.

If the lifeboats cannot be used, resort is to escape to the sea by launching liferafts and climbing down knotted ropes. The use of knotted ropes requires a certain degree of fitness and is not without risk. One area of development has been improved lifeboat systems. Prominent among these is the freefall lifeboat, which is launched with its complement straight into the water, as opposed to being lowered from davits. These have been in use on Norwegian platforms and are the method used on the replacement for Piper Alpha, Piper Bravo.

A variety of devices have become available for escape, ranging from individual packages which can be hooked onto a guard rail to chutes and slides.

Another aspect is the integrity of the escape routes from locations where personnel are likely to be to the means of escape. Escape routes need therefore to be designed against a variety of scenarios. Of particular importance are the routes to the lifeboats from the accommodation, where at any given time a large proportion of the personnel will be. One approach is to locate lifeboats in a protected area integral with the accommodation.

The *Piper Alpha Inquiry* heard a considerable amount of evidence on evacuation, escape and rescue. Contributors included Petrie (1989) (life-saving appliances), Rudd (1989) and Heiberg-Andersen (1990) (evacuation), Ginn (1989) (evacuation by helicopter), Kelleher (1989) (lifeboats), Side (1989) (evacuation and rescue), I.G. Wallace (1989) (evacuation and escape), Lien (1989) and Perrott (1989) (escape systems), Booth (1989) (escape routes) and J.D. Evans (1989) and de la Pena (1989) (smoke hoods). Work in this area has been described by Bellamy and Harrison (1988), Forland (1992), Forster and Wong (1992) and I.G. Wallace (1992).

A18.5.6 Explosion protection

In many earlier platform designs, there was little protection against explosion over and above that against fire, namely partition walls being designed as firewalls rather than as blast walls. This situation no longer pertains and much effort is being devoted to explosion protection. CFD simulation is being used to study the overpressures generated by explosions in modules, with particular reference to the enhancing effect of obstacles and to the mitigating effects of venting and of water spray systems.

A large amount of work has been done on the development and venting of explosions in modules and other obstructed spaces. Much of the work using CFD explosion simulation codes has been directed to the offshore module situation. Representative work using such codes is that of Hjertager (1982a, 1986, 1991), Bakke *et al.* (1989), Catlin (1990) and Hjertager *et al.* (1994). Examples of work on module explosions includes that described by Solberg, Pappas and Skramstad (1980, 1981), A.J. Harrison and Eyre (1987b), Catlin (1991), Brenton, Thomas and Al-Hassan (1992), Samuels (1992, 1993), Catlin, Manos and Tite (1993) and Catlin *et al.* (1993). A fuller account is given in Chapter 17.

Blast walls

An increasingly common method of explosion protection is the use of blast walls. The design of a blast wall is partly a matter of formulating suitable accident scenarios and predicting by simulation the resultant overpressure and partly one of engineering the wall so that it fulfils its protective function even if it deforms somewhat.

An account of the design of the blast walls on the Kittiwake platform was given to the *Piper Alpha Inquiry* by Doble (1989). The engineering of blast walls was described by van Beek (1989).

Smoke minimization and protection

Another area of work is the investigation of the hazard presented by smoke, particularly that from an oil pool fire. Aspects of this are the generation and movement of smoke and the exclusion of smoke from the accommodation.

A18.5.7 Design basis accidents

The design of plant to cope with accidental events requires that there be defined a set of design basis accidents. The concept is that the plant is then designed to withstand the design basis accidents in each category but does not have to be designed for events more severe than this. The selection of the design basis accidents is therefore closely linked with the estimates for the frequency of such events, so that overall risk in the design is an appropriate one.

Drilling

Drilling is a major activity on the platform that has no counterpart onshore. One aspect of this activity is the ever-present hazard of a well blowout.

Another aspect that can impinge on the operation of the platform as a whole is the need to avoid loss of power such that the drill becomes stuck.

Diving

Diving is another activity specific to an offshore platform. For the most part it does not impinge to any major extent on other activities except in so far as precautions are necessary to ensure the safety of the divers. At the time of the explosion on Piper Alpha the fire pumps had been turned to manual start to prevent sudden start-up of the pumps with consequent danger of a diver being drawn into the pump water inlet. This was not the policy on the sister platform Claymore, run by the same operator and in the same field.

Contractors

The proportion of contractors on a platform may well be of the order of 70% or more. Typically specialist teams such as drillers and divers are contractors with one person from the operating company as liaison. Some contractors may remain on a platform for long periods, others come and go. The operating company attempts to ensure the quality of contractors admitted to the platform by means of a quality assurance system. Personnel from the company visit the contractor company onshore and make the usual quality assurance audit.

It is the responsibility of a contractor to ensure that its personnel are properly trained in offshore emergency procedures as well as in safe systems of work and PTW systems. However, there may well be features of the systems operated on a platform that are particular to that platform. The operator needs, therefore, to ensure that contractors within its system are familiar with them.

A18.6 Offshore Emergency Planning

Offshore emergency planning has the same broad features as that for onshore. In principle, they include the detection of the incident, the assessment of its nature and seriousness and if necessary, the declaration of the emergency, the assumption of command and control, and the implementation of the emergency plan.

However, the emergency may not present in this ideally structured form. It may well take the form of an emergency shut-down initiated automatically or by personnel in the control room or at one of the shut-down buttons scattered throughout the platform.

A18.6.1 Emergency scenarios

The first step in emergency planning is the definition of the set of scenarios on which the plan is to be based. A wide range of scenarios need to be considered if the plan is to be robust. It is not uncommon for an incident to require the evacuation of the platform, but in the vast majority of cases this will be by helicopter and management may well feel it has not done as well as it might if even one person is injured.

At the other extreme is the sort of situation that arose on Piper Alpha where there was no prospect of an evacuation by any of the conventional means and where escape to the sea was the only option. This implies that the person in command explicitly instruct personnel to make their own escape.

A18.6.2 Goal-setting regulations

The basic framework operated in the new offshore safety administration is that of regulations which are goal-setting rather than prescriptive.

The first set of regulations of the new offshore administration are the *Offshore Installations (Safety Case) Regulations 1992*.

Before considering these, it is interesting to note that the first regulations issued, by the DoEn, in the wake of the Piper Alpha disaster were the *Offshore Installations (Pipe-line Valve) Regulations 1989*, which require the operator to fit EIVs to the pipelines connected to the platform and are thus prescriptive. The *Cullen Report* explicitly endorsed this, in effect considering that exceptionally this case met the conditions for adopting a prescriptive regulation.

A18.6.3 Safety case

The *Offshore Installations (Safety Case) Regulations 1992* implement Recommendation 1 of the Cullen Report that the operator should submit to the regulator a safety case.

For major hazard installations onshore a requirement for a safety case already existed under the *CIMAH Regulations 1984*. Evidence on the onshore safety case was given to the *Piper Alpha Inquiry* by Sefton (1989) and V.C. Marshall (1989d).

The offshore safety case is largely modelled on the onshore case, but has three features not explicitly contained in the latter.

Safety management system

One of these is the requirement on the operator to demonstrate that it has an SMS, which will assure the safety of the project through the design and operation. The SMS is thus part of the safety case rather than a free-standing requirement.

Temporary safe refuge

The second distinguishing feature of the offshore safety case is the requirement that the platform has a TSR, normally the accommodation, which should provide protection for a defined period. Design of a TSR involves the definition of the events against which it is to provide protection and specification both of the endurance period and the conditions which constitute failure.

Quantitative risk assessment

The third distinguishing feature of the offshore safety case is the requirement to use QRA. Essentially the QRA is a matter for the operator. The *Cullen Report* does, however, propose that one aspect of it be specified by the regulator.

The *Safety Case* involves a demonstration that the frequency of events that threaten the endurance of the accommodation, or TSR, will not exceed a certain value. In order to provide at least one fixed point in the administration, both the minimum endurance and the frequency with which there is a failure of such endurance should be specified by the regulatory body, at least in the first instance.

Accounts of offshore QRA include those of Pape (1992) (regulator), Sherrard (1992) (drillling units), R.F. Evans (1994) (model validation) and Gardner *et al.* (1994) (methodology).

A18.6.4 Costs of offshore safety

In the wake of Piper Alpha the offshore industry has incurred major expenditure to enhance safety. Much of this was incurred in response to the disaster itself and before the Cullen Report appeared.

The HSE itself has made a comparison of the quantifiable costs and benefit of safety measures in the UK North Sea expressed as Net Present Value over 15 years (HSC, 1992). It attributes the bulk of both costs and benefits to the *Safety Case Regulations*, the costs being estimated at £1200–2500 million and the benefits at £2600–4600 million. A commentary on these estimates is given by Potter (1994).

A18.7 Offshore Event Data

As for onshore installations, information on offshore events is of two main types: (1) incident data and (2) equipment failure data. The *World-wide Offshore Accident Databank (WOAD, 1988)* enumerates the principal accidents involving offshore structures involved in oil and gas activities. There is also a need, particularly in hazard assessment, for more detailed information on events such a leaks, fires and explosions, dropped loads and so on. The HSE has created the HCR database, as described by Bruce (1994).

Equipment failure data collection is the subject of a major co-operative exercise carried out under the aegis of OREDA and initiated some years before Piper Alpha. This is described in Appendix 14.

Appendix 19

Piper Alpha

Contents

At 10.00 p.m. on 6 July 1988 an explosion occurred in the gas compression module of the Piper Alpha oil production platform in the North Sea. A large pool fire took hold in the adjacent oil separation module, and a massive plume of black smoke enveloped the platform at and above the production deck, including the accommodation. The pool fire extended to the deck below, where after 20 min it burned through a gas riser from the pipeline connection between the Piper and Tartan platforms. The gas from the riser burned as a huge jet flame. Most of those on board were trapped in the accommodation. The lifeboats were inaccessible due to the smoke. Some 62 men escaped, mainly by climbing down knotted ropes or by jumping from a height, but 167 died, the majority in the quarters.

The Piper Alpha explosion and fire was the worst accident which has occurred on an offshore platform.

Following the disaster a Public Inquiry was set up under the Public Inquiries Regulations – Offshore Installations Regulations 1974 presided over by Lord Cullen to establish the circumstances of the disaster and its cause and to make recommendations to avoid similar accidents in the future. The Inquiry's report *The Public Inquiry into the Piper Alpha Disaster* (the *Piper Alpha Report,* or *Cullen Report*) (Cullen, 1990) is the most comprehensive inquiry conducted in the United Kingdom into an offshore platform disaster, or indeed into any process industry disaster, onshore or offshore.

The Piper Alpha Inquiry has been of crucial importance in the development of the offshore safety regime in the UK sector of the North Sea. Whereas Flixborough was followed first by a Court of Inquiry and then by the Advisory Committee on Major Hazards, the Piper Alpha Inquiry not only discharged the function of an inquiry into the specific disaster, but made recommendations for fundamental changes to the offshore safety regime which were accepted by the government.

The description of the Piper Alpha disaster given below is necessarily a relatively brief one. Nevertheless, it is somewhat fuller than that of the case histories in the other appendices, for several reasons. It provides a good illustration of the work of an accident inquiry. It is replete with lessons on design and operation of hazardous installations. And it has had far-reaching consequences for the offshore safety regime. A fuller account is given in the *Piper Alpha Report*. The daily transcripts, available in copyright libraries, also repay study. An account from the viewpoint of one of the consultants to the Inquiry has been given by Sylvester-Evans (1991).

Selected references on Piper Alpha are given in Table A19.1.

A19.1 The Company, the Management and the Personnel

The Piper Alpha oil platform was owned by a consortium consisting of Occidental Petroleum (Caledonia) Ltd, Texaco Britain Ltd, International Thomson plc and Texas Petroleum Ltd and was operated by Occidental.

The management concerned with the Piper platform included

Offshore Installation Manager	Mr C.D. Seaton
Offshore Superintendent	Mr T.J. Scanlon
Senior Maintenance Superintendent	Mr R.H. Seddon
Maintenance Superintendent	Mr K.D. White Mr A.C.B. Todd

Table A19.1 *Selected references on Piper Alpha*

Jones (1990) (training); Keenan (1989) (standby vessels); Kelleher (1989) (lifeboats); Kinloch (1989a) (PTW); Kyle (1989) (PTWs); Lien (1989) (escape systems); Littlejohn (1990) (offshore supervisors); Lyons (1989) (offshore safety regime); McIntosh (1989) (fire and explosion protection); McKee (1990) (safety management); Macey (1989) (standby vessels); Matheson (1989) (offshore emergency medical team); V.C. Marshall (1989d) (safety cases); Middleton (1989) (standby vessels); Nordgard (1990) (accommodation in Norwegian sector); Ognedal (1990) (Norwegian offshore safety regime); Pape (1989) (HSE view on QRA); de la Pena (1990) (smoke hoods); Perrott (1989) (escape systems); Petrie (1989, 1990) (life-saving appliances, offshore safety regime); Priddle (1990) (offshore safety regime); Rimington (1990) (onshore safety regime); Rudd (1989) (evacuation); Scanlon (1989) (PTWs); Sefton (1989) (CIMAH, safety cases); R.A. Sheppard (1989) (safety management); Side (1989) (rescue and evacuation); Spouge (1989) (options for accommodation); B.G. Taylor (1989) (offshore industry developments); Tveit (1990) (Norwegian offshore safety regime, QRA); Vasey (1989) (mitigation of module explosions); I.G. Wallace (1989) (evacuation and escape); Willatt (1989) (offshore pipeline connections)

Further accounts

Anon. (1988g); Johnsen (1989, 1990); Boniface (1990a,c–e); Redmond (1990, 1991 LPB 102); S.M. Richardson, Saville and Griffiths (1990); Sylvester-Evans (1990a,b, 1991); Tombs (1990); Lees (1991,1992a, 1994b)

Other personnel on duty on the evening of July 6 and referred to below include

Lead maintenance hand	Mr A.G. Clark
Lead production operator	Mr R.A. Vernon
Phase 1 operator	Mr R.M. Richard
Phase 2 operator	Mr E.C. Grieve
Control room operator	Mr G. Bollands
Instrument technician	Mr W.H. Young

A19.2 The Field and the Platform

The Piper Alpha platform was located in the Piper field some 110 miles north-east of Aberdeen. The platforms in the field and the pipeline connections between them are shown in Figure A19.1.The Piper platform separated the fluid produced by the wells into oil, gas and condensate. The oil was pumped by pipeline to the Flotta oil terminal in the Orkneys, the condensate being injected back into the oil for transport to shore. The gas was transmitted by pipeline to the manifold compression platform MCP-01, where it joined the major gas pipeline from the Frigg Field to St Fergus.

There were two other platforms connected to Piper Alpha. Oil from the Claymore platform, also operated by Occidental, was piped to join the Piper oil line at the 'Claymore T'. Claymore was short of gas and was therefore connected to Piper Alpha by a gas pipeline so that it could import Piper gas. Oil from Tartan was piped to Claymore and then to Flotta and gas from Tartan was piped to Piper and thence to MCP-01.

Elevation views of the Piper Alpha platform, the layout of the production deck at the 84 ft level and the layout of the deck below, the 68 ft level, are shown in Figures A19.2, A19.3 and A19.4 respectively. The production deck level consisted of four modules, Modules A–D. A Module was the wellhead, B Module the oil separation module, C Module the gas compression module and D Module the power generation and utilities module.

A Module was about 150 ft long east to west, 50 ft wide north to south and 24 ft high. The other modules were of approximately similar size. There were firewalls between A and B Modules, between B and C Modules and between C and D Modules (the A/B, B/C and C/D firewalls, respectively); these firewalls were not designed to resist blast.

The pig traps for the three gas risers from Tartan and to MCP-01 and Claymore were on the 68 ft level. Also on this level were the dive complex and the JT flash drum, the condensate suction vessel and the condensate injection pumps.

There were four accommodation modules: the East Replacement Quarters (ERQ), the main quarters module; the Additional Accommodation East (AAE); the Living Quarters West (LQW) and the Additional Accommodation West (AAW).

The control room was in a mezzanine level in the upper part of D Module. It was located about one quarter of the way along the C/D firewall from the west face.

There were two flares on the south end of the platform, the east and west flares, and there was a heat shield around A Module to provide protection against the heat from the flares.

Platform systems included the electrical supply system, the fire and gas detection system, the fire water deluge system, the emergency shut-down system, the communications system and the evacuation and escape system.

Electrical power was supplied by two main generators which normally ran off the gas supply but could be fired by diesel. There was a diesel-fired emergency generator and also a drilling generator and an emergency drilling generator. In addition, there were uninterrupted power supplies for emergency services.

The main production areas were equipped with a fire and gas detection system. In C Module the gas detection system was divided into five zones: Cl and C2 in the west and east halves of the module and C3, C4 and C5 at the three compressors, respectively.

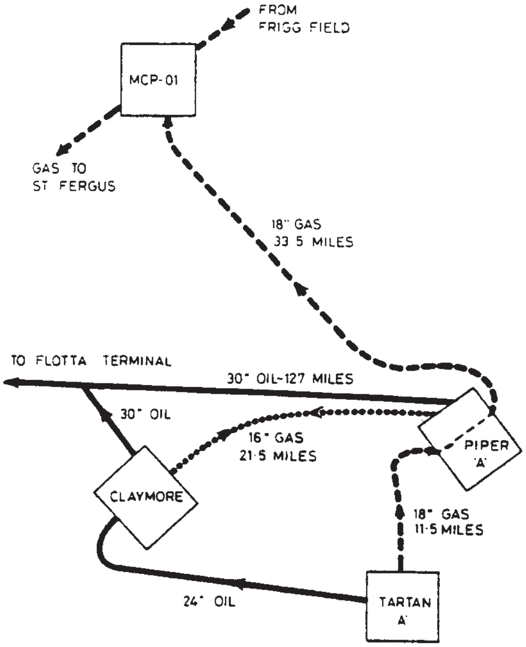

Figure A19.1 *Pipeline connections of the Piper field (Sylvester-Evans,1991)(Courtesy of the Institution of Chemical Engineers)*

The fire water deluge system consisted of ring mains which delivered foam in A–C Modules and part of D module and at the Tartan and MCP-01 pig traps and water at the condensate injection pumps. The fire pumps were supplied from the main electrical supply but there were backup diesel-driven pumps.

The hydrocarbon inventory in the pipelines was approximately as follows. The main oil line was 30 in. in diameter and 30 miles long and held some 70,000 te of oil. The gas line from Tartan was 18 in. in diameter and 11.5 miles long and held some 450 te; the gas line to MCP-01 was 18 in. in diameter and 33.5 miles long and held 1280 te; the gas line to Claymore was 16 in. in diameter and 21.5 miles long and held 260 te.

A19.3 The Process and the Plant

The fluid from the wellhead, containing oil, gas, condensate and water, passed through the wellhead 'Christmas trees' to the two separators where the gas was separated from the oil and water. The oil was then pumped into the main oil line. The gas was compressed first in three centrifugal compressors to 675 psia, with some gas being taken off at this point as fuel gas for the main generators, and then boosted in the first stage of two reciprocating compressors to 1465 psia. Condensate was removed and the gas was then further compressed in the second stage of the reciprocating compressors to 1735 psia. The gas then went three ways: to serve as lift gas at the wells, to MCP-01 as export gas or to flare. The plant could be operated in two modes, which affected the method of removing condensate. In the normal, or phase 2, mode, the gas passed from the first stage of the reciprocating compressors to the Gas Conservation Module (GCM), where it was dried. The gas was then cooled by reducing the pressure across a turbo-expander so that condensate was knocked out by the expansion and returned to the outlet of the JT flash drum, which was also the inlet of the second stage of the reciprocating compressors. Condensate from the GCM was passed to the JT flash drum. The process could also revert to the original, or phase 1 mode, dating from a period before the GCM was installed to produce export quality gas, in which the GCM was isolated and gas from the first stage of the reciprocating compressors was let down in pressure across the JT valve into the JT flash drum so that condensate was knocked out by the Joule–Thomson (JT) effect and then passed as before into the second stage of the reciprocating compressors. Condensate from the JT flash drum passed first to two parallel centrifugal condensate booster pumps and then to two reciprocating condensate injection pumps which pumped the condensate into the main oil line. There was normally one condensate injection pump line operating and one on standby.

Each condensate injection pump was protected from overpressure on the delivery side by a single pressure safety valve (PSV). The PSV was on a separate relief line from the delivery head of the pump rather than on the delivery line itself. The valve on A pump was PSV 504 and that on B pump PSV 505. These valves were located in C Module, the relief line running up from the 68 ft level, where the pumps were located, to the PSVs in C Module and back down to the condensate suction vessel on the 68 ft level.

In accordance with standard practice, methanol was injected into the process at various points to prevent formation of hydrates which would tend to cause blockages.

A19.4 Events Prior to the Explosion

On 6 July there was a major work programme on the platform. This included the installation of a new riser for the Chanter field and work on a prover and metering loop.

The extra accommodation for the workforce was provided on the Tharos, a large floating fire fighting vessel anchored near the platform. Also near the platform were the standby vessel, the Silver Pit, a pipeline vessel, the Lowland Cavalier, and Maersk anchor handling vessels for the Tharos.

The GCM was also out of service for changeout of the molecular sieve driers. In consequence, the plant operation had reverted to the phase 1 mode so that the gas was relatively wet.

The resulting increased potential for hydrate formation was recognized by management onshore. The increased methanol injection rates required were calculated and communicated to the platform together with suggestions for the configuration of the methanol pumps. The methanol injection rates needed were some 12 times greater than for normal phase 2 operation.

However, there was an interruption of the methanol supply to the most critical point, at the JT valve, between 4.00 and 8.00 p.m. that evening.

The operating condensate injection pump was B pump. The A pump was down for maintenance. There were three maintenance jobs to be done on this pump: (1) a full 24 month preventive maintenance (PM), (2) repair of the pump coupling and (3) recertification of PSV 504. In order to carry out the 24 month PM, the pump had been isolated

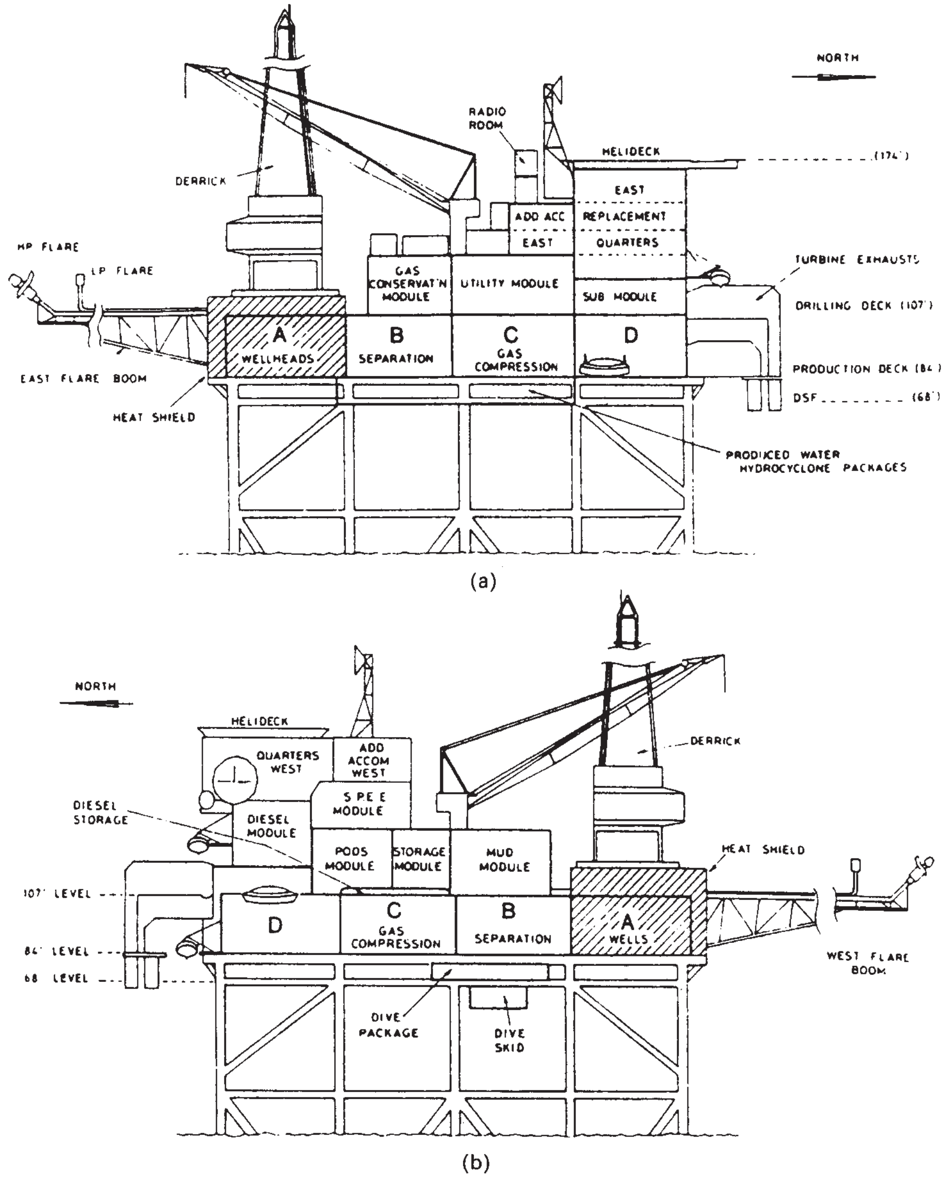

Figure A19.2 *The Pipe Alpha platform: (a) east elevation and (b) west elevation (Sylvester-Evans,1991) (Courtesy of the Institution of Chemical Engineers)*

by closing the gas operated valves (GOVs) on the suction and delivery lines but slip plates had not been inserted. Work on the coupling, which was suffering from a vibration problem, would not involve breaking into the pump.

With the pump in this state, with the GOVs closed but without slip plate isolation, access was given to remove PSV 504 for testing. It was taken off in the morning of July 6 by a two-man team from the specialist contractor Score UK Ltd. They were not able to restore the PSV that evening. The supervisor in this team came back to the control room some time before 6.00 p.m. to suspend the permit-to-work (PTW) and the team then went off duty, intending to put the PSV back the next day.

At about 4.50 p.m. that day, just at shift changeover, the maintenance status of the pump underwent a change. The maintenance superintendent decided that the 24 month PM would not be carried out and that work on the pump should be restricted to the repair of the pump coupling.

About 9.50 p.m. that evening B pump on the 68 ft level tripped out. The lead production operator and the phase 1 operator attempted to restart it but without success. The loss of this pump meant that with A pump also down

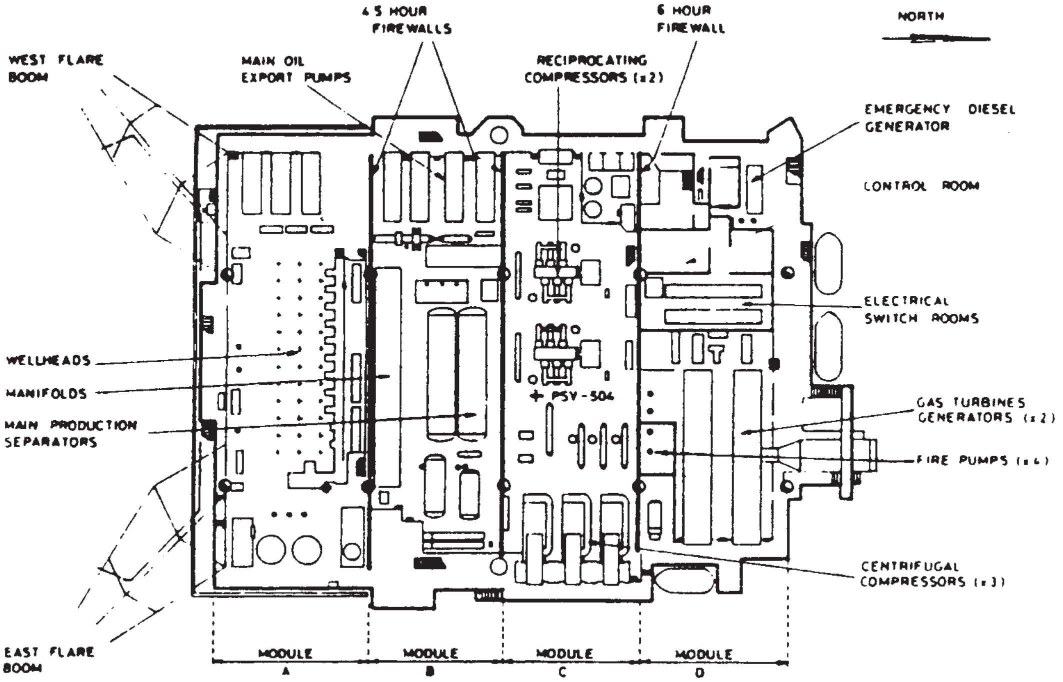

Figure A19.3 *The Piper Alpha platform: the production deck on the 84 ft level (Sylvester-Evans,1991) (Courtesy of the Institution of Chemical Engineers)*

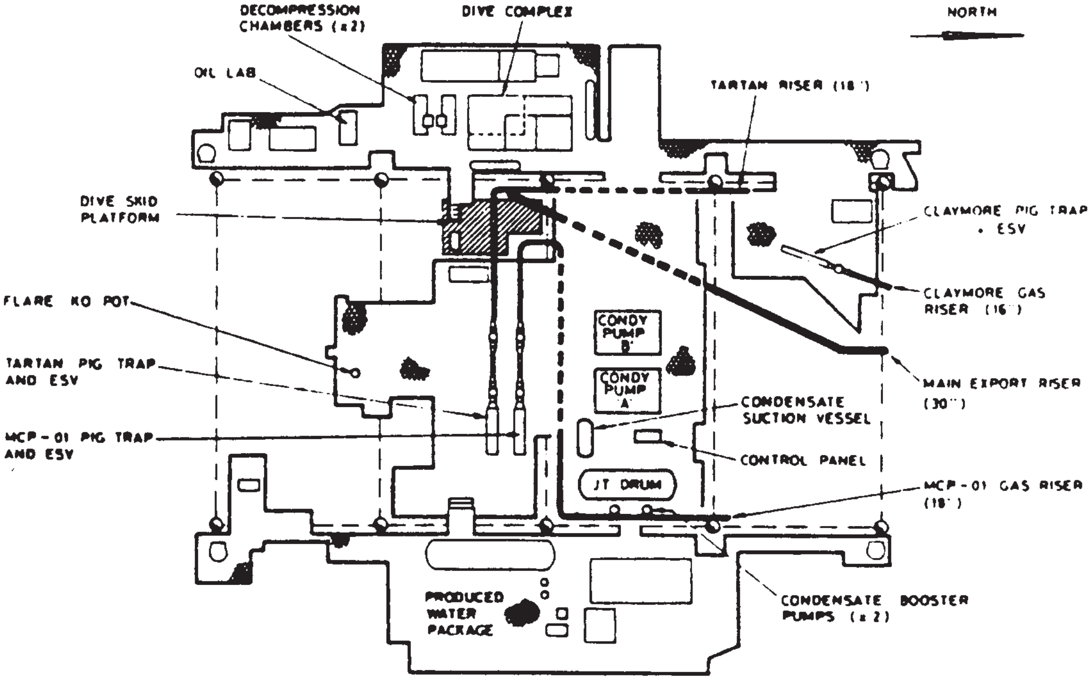

Figure A19.4 *The Piper Alpha platform: the 68 ft level (Sylvester-Evans,1991) (Courtesy of the Institution of Chemical Engineers)* condensate would back up in the JT flash drum and within some 30 min would force a shut-down of the gas plant. There was a possibility that if the gas supply to the main generator was lost and if the changeover to the alternative diesel fuel failed, the wells also would have to be shut-down. It would then be necessary to undertake a 'black start'.

The lead operator came up to the control room. He talked on the telephone with the lead maintenance hand and it was agreed to attempt to start A pump. The lead operator signed off the permit for A pump so that it could be electrically deisolated and restarted, and went back down to the pumps. The lead maintenance hand came down to the control room to organize the electricians to deisolate the pump. It is uncertain precisely what action the lead operator and the phase 1 operator took. They were observed at the pumps by the phase 2 operator and an instrument fitter, but the evidence of these witnesses was inconclusive. However, there was no doubt that the lead operator intended to start A pump.

About 9.55 p.m. the signals for the tripping of two of the centrifugal compressors in C Module came up in the control room. This was followed by a low gas alarm in C3 zone on C centrifugal compressor. Then, the third centrifugal compressor tripped. Before the control room operator could take any action a further group of alarms came up: three low gas alarms in zones C2, C4 and C5 and a high gas alarm. The operator had his hand out to cancel the alarms when he was blown across the room by the explosion.

Just prior to the explosion personnel in workshops in D Module heard a loud screeching sound which lasted for about 30 s.

A19.5 The Explosion, the Escalation and the Rescue

The initial explosion occurred at 10.00 p.m. It destroyed most of the B/C and C/D firewalls and blew across the room the two occupants of the control room, the control room operator and the lead maintenance hand.

The emergency shut-down (ESD) system operated, closing the emergency shut-off valve (ESV) on the main oil line and starting blowdown of the gas inventories to flare. The ESVs on the gas pipelines were not designed to close on platform ESD; this would impose an undesirable forced shut-down on the other platforms connected to Piper. Instead there were three separate shut-down buttons for these ESVs in the control room.

The explosion was followed almost immediately by a large fireball which issued from the west side of B Module and a large oil pool fire at the west end of that module. The explosion and fire were witnessed by personnel on the vessels lying off the platform. It so happened that one witness on the Tharos was standing with camera at the ready. He took a sequence of shots of the development of the fireball.

The large oil pool fire gave rise to a massive smoke plume which enveloped the platform from the production deck at the 84 ft level up.

The offshore installation manager (OIM) made his way to the radio room and had a Mayday signal sent.

The Tharos effectively took on the role of On-Scene Commander. The Coast Guard station and Occidental headquarters onshore were informed. Rescue helicopters and a Nimrod aircraft for aerial on-scene command were dispatched. The flight time for the helicopters was about an hour.

Most of the personnel on the platform were in the accommodation, the majority in the ERQ. Within the first minute flames appeared on the north face of the module also and the module was enveloped in the smoke plume coming from the south. The escape routes from the module to the lifeboats were impassable.

At the 68 ft level divers were working with one man under water. They followed procedure, got the man up and briefly through the decompression chamber. They were unable to reach the lifeboats, which were inaccessible due to the smoke. They therefore launched life rafts and climbed down by knotted rope to the lowest level, the 20 ft level.

The drill crew also followed procedure and secured the wellhead.

The oil pool in B Module began to spill over onto the 68 ft level where a further fire took hold. There were drums of rigwash stored on that level which may have fed the fire.

The fire water drench system did not operate. There was only a trickle of water from the sprinkler heads.

The explosion disabled the main communications system which was centred on Piper. The other platforms were unable to communicate with Piper. They became aware that there was a fire on Piper, but did not appreciate its scale. They continued for some time in production and pumping oil. This pumping would have caused some additional oil flow from the leak at Piper.

After some 20 min from the initial explosion the fire on the 68 ft level led to the rupture of the Tartan riser on the side outboard of the ESV. This resulted in a massive jet flame which enveloped much of the platform.

The emergency procedure was for personnel to report to their lifeboat, but in practice most evacuations would be by helicopter and personnel would be directed from the lifeboats to the dining area on the upper deck of the ERQ and then to the helideck. Personnel in the ERQ found the escape routes to the lifeboats blocked and waited in the dining area. The OIM told them that a Mayday signal had been sent and that he expected helicopters to be sent to effect the evacuation. In fact the helideck was already inaccessible to helicopters.

Some 33 min into the incident the Tharos picked up the signal 'People majority in galley. Tharos come. Gangway. Hoses. Getting bad'.

No escape from the ERQ to the sea was organized by the senior management. However, as the quarters began to fill with smoke individuals filtered out by various routes and tried to make their escape.

Some men climbed down knotted ropes to the sea. Others jumped from various levels, including the helideck at 174 ft. One man who had arrived only that afternoon on his first tour jumped from a high level. One standing on pipes protruding from the pipe deck was pushed off by another behind him who could no longer stand the heat of the pipes.

The vessels around the platform launched their fast rescue craft (FRCs). The first man rescued, by the FRC of the Silver Pit, was the oil laboratory chemist, who, on experiencing the explosion, simply walked down to the 20 ft level and was picked up without getting his feet wet. Most survivors, however, were rescued from the sea. Much of the rescue operation took place after the rupture of the Tartan riser.

The FRC of another vessel, the Sandhaven, was destroyed with only one survivor. The FRC of the Silver Pit made repeated runs to the platform; eventually it was blown out of the water, and began to sink, but returned to the platform and then finally sank, its crew being themselves rescued by helicopter.

At about 10.50 p.m. the MCP-01 riser ruptured and about 11.18 p.m. the Claymore riser ruptured. The pipe deck collapsed and the ERQ tipped. By 12.15 a.m. on 7 July the north end of the platform had disappeared. By the morning only A Module, the wellhead, remained standing.

A19.6 The Investigation

An investigation of the disaster was immediately undertaken by the Department of Energy (DoEn) headed by Mr Petrie. Two reports were issued, an interim report (the *Petrie Interim Report*, or simply, *the Petrie Report*) and a final report (*the Petrie Final Report*); the latter included appendices on various technical studies commissioned.

The *Petrie Report* put forward two scenarios for the hydrocarbon leak which led to the explosion: a leak from the site of PSV 504 (Scenario A) and a leak due to ingestion of liquid into the reciprocating compressors (Scenario B).

The Inquiry was presided over by a Scottish judge, Lord Cullen, assisted by three technical assessors. There was a legal counsel to the Inquiry assisted by technical consultants to the Inquiry. Parties to the Inquiry included Occidental, the DoEn, groups representing survivors and the trade unions, the contractors, the specialist contractor Score, several equipment manufacturers and for the second part, the UK Oil Operators Association (UKOOA). Part 1 of the Inquiry dealt with the disaster and its background, Part 2 with the future. The Inquiry heard some 280 witnesses in 180 days of evidence and received some 840 productions, or documents.

It began by considering whether to advise that the debris of the platform should be raised from the sea bed. It was clear at an early stage that the size of leak sought was of the order of 10 mm^2. The evidence was that the operation presented a number of problems and hazards, would involve considerable delay and might well not provide much useful information. The Inquiry decided not to pursue the matter.

In seeking to find the cause of the leak, the *Piper Alpha Report* begins with the evidence on the explosion itself. It concludes that the explosion was at 10.00 p.m., that it was in C Module and in the south-east quadrant of that module, that the fuel involved was condensate, that the leak gave rise to a gas cloud filling less than 25% of the module, that the mass of fuel within the flammable region was some 30–80 kg, that the explosion was a deflagration rather than a detonation, that the maximum peak overpressure was in the range 0.2–0.4 bar and that the ignition source could not be identified. Evidence for these findings included the gas alarms in C Module; the screeching noise heard just prior to the explosion; testimony of and photographs taken by observers on the surrounding vessels of the fires just after the explosion; the effects of the explosion, including the damage to the two firewalls in C Module; the effects of the explosion on the control room and its occupants; the lack of damage to the heat shield on A Module and estimates of overpressure based on some of the explosion effects, such as firewall damage and bodily translation of persons.

It was not initially clear how a gas cloud of sufficient size could develop without setting off certain gas alarms which according to the evidence had not been triggered. In particular there was a gas detector in the roof above the site of PSV 504 or PSV 505 (the two valves were close together) and another some 2–3 ft above floor level among the heat exchangers between the reciprocating and centrifugal compressors; both these detectors were in C2 zone. However, the first gas alarm was in C3 zone at C centrifugal compressor. Accordingly, wind tunnel tests were commissioned from BMT Fluid Mechanics to explore the pattern of gas alarms for different types of leak. Scenarios investigated included leaks of natural gas and of condensate, the one a buoyant and the other a heavy gas; leaks from various points in the modules and leaks from various types of source, including a leaking flange and an open pipe. It was concluded by the investigator that of the scenarios studied only a leak from the site of PSV 504 or PSV 505 fitted the pattern of gas alarms and, further, that this leak was a two-stage leak, the first stage being small and the second relatively large. It would have been this second stage which gave rise to the gas cloud sought.

The experimental run of main interest simulated a leak of 100 kg/min from PSV 504. Figure A19.5 shows the contours of the lower flammability limit of the gas cloud formed after 30 s from such a leak. The cloud would not set off either of the gas detectors mentioned. Figure A19.6 shows the mass of gas within the flammable limit as a function of the leak flow rate after 30 s and at infinite time. These results were subject to a number of reservations but indicated that a gas cloud of sufficient size could be formed.

The next question considered was whether the explosion of such a gas cloud could cause the damage observed. It was estimated that the B/C firewall would fail at an overpressure of 0.1 bar and the C/D firewall at an overpressure of 0.12 bar.

Simulations of the explosion of flammable mixtures in the module had been commissioned prior to the Inquiry at the Christian Michelsen Institute (CMI) by the DoEn and other parties. The simulations were performed using the FLACS computer code. Following the wind tunnel work, the Inquiry commissioned a single further run for a gas cloud in the south-east quadrant of C Module and containing some 45 kg of propane within the flammable limit. The simulation was subject to a number of reservations but indicated that such an explosion could cause the firewall damage observed.

The simulation also provided an explanation of a point which had seemed puzzling. The two occupants of the control room were thrown across it by the explosion and experienced a rush of cold air, not hot gas. The simulation showed that in the early stages of the explosion the control room wall would be subject to a positive overpressure and inrush of air, but that by the time the hot combustion products approached the control room, the negative phase of the pressure pulse had set in, the velocity vectors had reversed and the direction of air flow was out of the control room into C Module.

The two-stage nature of the leak also presented another point of difficulty. Isolation of A pump was by the closure of the GOVs on the suction and the delivery lines. The suction GOV was electrically isolated and it was uncertain whether power to it had been restored by the time of the initial explosion. In any event restoration of the valve would involve reconnecting a pneumatic line to the valve, which could quickly be done by an operator. It was concluded that this connection was made and that probably the operator gave it a tweak to make sure the valve movement was restored. This would have had the effect of admitting

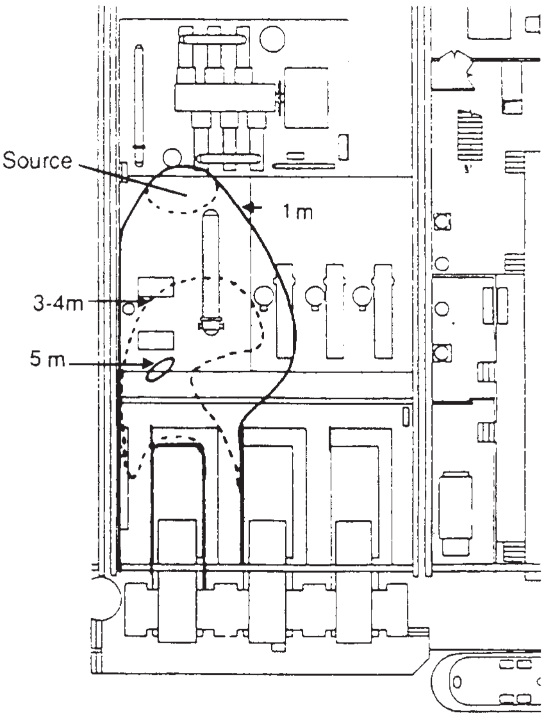

Figure A19.5 *The flammable gas cloud for a leak of 100 kg/min in the BMT wind tunnel tests: LEL contours at 30 s (Cullen, 1990)*

condensate to the relief line to PSV 504, but not of filling it with condensate liquid, thus giving rise to the early, smaller leak. Subsequent opening of the valve and filling of the relief line with condensate liquid could then have caused the later, larger leak.

Evidence was also heard on tests on leaks from blind flanges. The flange at PSV 504 was a ring-type joint (RTJ) flange. Three methods of tightening up were investigated: flogging up with a flogging spanner and hammer; hand tightening with a combination spanner and finger tightening. The results showed that a flange in good condition which had been flogged up or hand tightened did not leak. Even deterioration of the flange would be unlikely to give the leak sought unless the deterioration was gross. However, a finger-tightened flange could give a leak which was directionally downwards and was of the flow rate sought.

The Inquiry concluded that the explosion had been caused by ignition of a gas cloud containing some 45 kg of hydrocarbon within the flammable range, arising from a two-stage leak, in the first stage perhaps some 4 kg/min and in the second stage some 110 kg/min lasting some 30 s, coming from an orifice of equivalent diameter some 8 mm^2.

There was no obvious explanation why the blind flange was not leak-tight. Much evidence was led to the effect that an experienced and competent fitter would not make up a blind flange which was not leak-tight. The Inquiry noted, however, that the decision not to proceed with the full 24 month PM on A pump was taken just as shift handovers on the platform were starting so that some personnel may have been ignorant of this change in intent and that the lack of leak-tightness of the blind flange may have been connected with the status of A pump.

The lead production operator had clearly had the intention to start A pump. It was difficult to explain this given fact that its sole PSV was off. The Inquiry concluded that the lead operator was indeed ignorant of this, even though

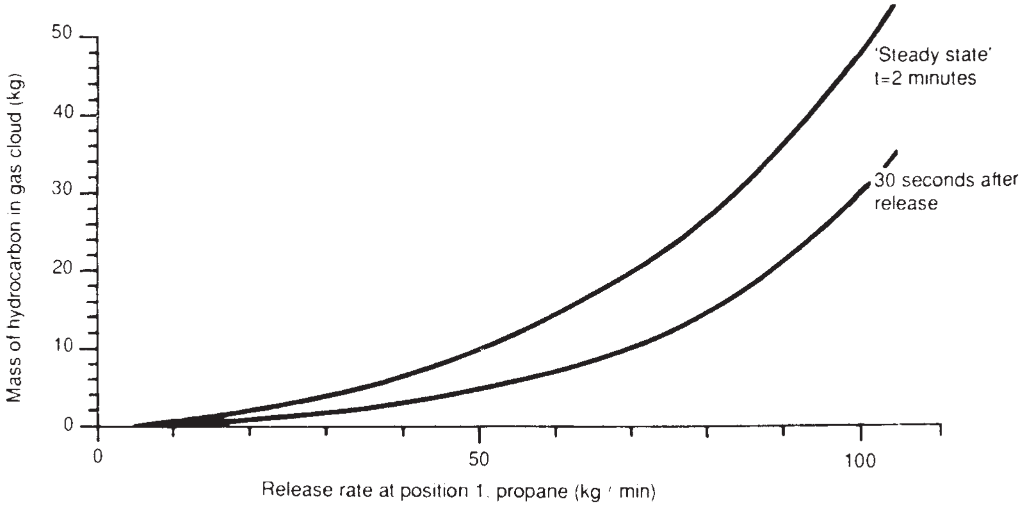

Figure A19.6 *Mass of fuel in the flammable range in the BMT wind tunnel tests: (a) variation with time (b) variation with leak rate (Cullen, 1990)* this meant a serious breakdown of communications about the work. It implied that the fact that the PSV was off was not communicated in the handovers of the lead maintenance hand, the phase 1 operator and the lead production operator and that the lead operator did not learn of it through the PTW system.

When he found that he was unable to put the PSV back that evening, the Score supervisor came up to the control room to suspend the permit. He was on his first tour as a supervisor and had had no training in the operation of the PTW system in use on the platform. Whom he spoke to and what transactions took place were obscure. It was unclear how he knew that the procedure in filling out the permit for suspension was to write 'SUSP' in the gas test column.

In any event the Score supervisor did not make a final inspection of the job site before going off work and evidently the lead production operator did not inspect the job site either, although in both cases good practice required that this be done.

Further, the leak would not have occurred if there had been a more positive isolation of the pump by means such as the use of a slip plate.

The explanation just described is that adopted in the *Piper Alpha Report* but several other scenarios for the leak were also explored. One group of scenarios was concerned with explanations of the leak from the blind flange following admission of condensate into A pump other than lack of leak-tightness. They include the possibilities of auto-ignition, shock loading, low temperature brittle fracture, and overpressurization by methanol injection. All of these were quickly ruled out except auto-ignition by compression of a flammable mixture formed in the relief line. The line had been left open for an hour before the blind flange was put back on. It was not possible to calculate whether auto-ignition would have occurred due to lack of data on auto-ignition properties of the multi-component mixture at the high pressures involved, some 300 bar. Moreover, company documentation on the rating of the pipework was inconsistent so that it was uncertain whether the flange was a 900 or 1500 lb one. The expert evidence was that if auto-ignition had occurred and the lower rating applied, a leak was possible, although whether it would have had the required characteristics was another matter. An account of this work on auto-ignition has been given by S.M. Richardson, Saville and Griffiths (1990).

The scenario was considered that condensate liquid had backed up in the JT flash drum and thence into the reciprocating compressors. There was evidence that on loss of B pump steps had been taken to reduce the condensate make by unloading and recycling these compressors. The report concludes that there had been insufficient time for backup to occur before the initial explosion and that in addition both the conditions around the compressors and the expected action of protective instrumentation were against this scenario.

A further scenario which emerged in the Inquiry was that the leak occurred from PSV 505 and that it was caused by hydrate blockage. The interruption to the methanol supply to the JT valve lent credibility to this scenario. Experimental work commissioned showed that hydrates would form under the conditions pertaining at the JT valve during the partial loss of methanol supply if the temperature at the valve fell below a critical value; it had in fact been below this temperature on 5 July. The expert evidence was that hydrates could pass through to the condensate injection pumps and cause blockage there some 2 h after restitution of the full methanol supply. There were several versions of the scenario all leading to blockage of hydrate at PSV 505 and overrunning of the pump so that the delivery pressure rose to a value high enough to cause rupture of the valve, which was the weakest point in the line. The report does not rule out this scenario, but regards it as less likely than the preferred one.

Finally, the consultants to the Inquiry reviewed a large number of other scenarios which were not purely theoretical but had some link with the information available at the time, which included a hazop study, past equipment failures and process conditions that evening. None was found convincing by the Inquiry.

Turning to the escalation, the causes of the oil pool fire and the fireball which occurred in B Module within seconds of the explosion in C Module were unclear. The Inquiry heard evidence on the type, number, velocity and impact effects of the projectiles which would have resulted from the destruction of the B/C firewall. The condensate injection line ran from C Module through into B Module where it joined the main oil line. The report concludes that probably the fireball was caused by a missile rupturing this line near the main oil pumps at the west face of B Module.

Estimates of the size of the oil pool fire indicated that the supply of oil to the fire probably exceeded the oil inventory of the separators and that there was a leak of oil from the main oil line through the main oil line EVS which was not fully closed. This leak would be aggravated by continued pumping of oil by the other platforms.

The fire water deluge system did not work. The initial explosion knocked out the main power supplies. It may also have damaged the water pumps and the water mains. In any event it was the practice on Piper to put the pumps on manual start when divers were in the water and thus in possible danger of being sucked into the pump intakes and they were on manual start that evening. The start controls were at the pumps themselves. After the explosion occurred an attempt was made to get through to the pumps to start them by personnel wearing breathing apparatus, but to no avail. Further evidence was given of quite extensive blockage caused by corrosion products in the fire water deluge system, which operated on sea water, a problem which had persisted for some years.

The initial explosion caused the operation of the platform ESD. This could have occurred through loss of the main power supply and/or rupture of a pneumatic ring main. Also, although dazed by the explosion the control room operator pressed the platform ESD button. He did not, however, press the buttons to close the ESVs on the three gas pipelines. Evidently, these did close but their closure was due rather to the effects of the initial explosion on power supplies to the valves.

Following the initial explosion a period of extended flaring occurred which greatly exceeded that to be expected from the flaring of the gas inventory on the platform. The report accepted that the most probable explanation was a failure of the Claymore ESV to close fully.

The main communications for the Piper field were centred on Piper. The system was knocked out by the initial explosion, so that the other platforms were unable to communicate with Piper and had difficulty communicating with the shore.

The report details a number of management weaknesses. There were severe and numerous defects in the PTW system. For example, it violated more than half of the main points in the code of practice on PTWs issued by the Oil Industry Advisory Committee (OIAC). The system was operated rather casually. The training of the specialist contractors supervisor in the permit system operated on the platform was found to be inadequate.

With regard to handovers, the company had been prosecuted only a year before for a fatality and had pleaded guilty. The report takes the view that a failure in handover procedures was a factor in that accident.

A number of different types of audit were performed by the company, by its partners, by loss prevention specialists and so on. None of these had revealed the defects in the PTW which became apparent very quickly at the Inquiry.

The report is critical of the handling of the emergency by the senior management on the platform and in particular of the failure to recognize that helicopter evacuation was not possible and to take command of the situation and organize escape from the ERQ.

The decision to keep the platform operating despite the large workload is another matter of which the report is critical.

The report states that the company had no system to ensure that all projects were subject to formal safety assessment. Certain techniques such as hazop were used on some projects and quantitative estimates had been made in some studies, but the approach was unsystematic. The report takes the view that as a consequence the hazards presented by the hydrocarbon inventory on the platform and particularly in the pipelines had not been systematically addressed.

Part 2 of the Inquiry was concerned with the future offshore safety regime. The context was not only the Piper Alpha disaster but also the changes taking place in the North Sea oil province. The exploitable oil and gas fields were becoming smaller and the technology to develop them was becoming more varied.

The evidence in Part 1 revealed serious weaknesses in the company management. It was an issue why the DoEn had not discovered these weaknesses. The report is critical of the relative lack of emphasis placed by the Department on the assessment of management and management systems.

In contrast to the British onshore and Norwegian offshore regimes, which had both moved increasingly towards goal-setting regulations, the British offshore regime relied excessively on prescriptive regulations, and associated guidance.

The deficiencies of such a regime were illustrated in the regulations concerning fire protection, which had a number of defects. Passive and active fire protection were covered by two separate sets of regulations. The regulations, and associated guidance, for active fire protection led in practice to systems based on delivery of a uniform quantity of water over large areas of a platform, deluge systems prone to blockage and massive water pumps. Fire protection was not integrated with explosion protection.

The report states that the approach taken by the DoEn to the control of the major hazards from hydrocarbons at high pressure did not impress as an effective one. Further, the inspectorate had relatively little expertise in this area.

Following the Piper Alpha disaster the DoEn brought in regulations to require ESVs to be placed nearer to sea level and for the valves to be of full ESV standard. The report notes that of the 400 risers covered by the regulations, some 70 required modification in the latter respect.

The regime made little use of formal safety assessment (FSA). This was in contrast to the regulatory use of FSA onshore, and in particular the onshore safety case. The DoEn had in fact explicitly rejected the concept of an offshore safety case. This policy also contrasted with the situation in the Norwegian sector, where a concept safety evaluation (CSE) was required. Quantitative risk assessment is required in a CSE and is often necessary to fulfil the requirements of a safety case.

Considerable evidence was heard on quantitative risk assessment (QRA). The burden of this evidence was that QRA is in regular use in many companies as an aid to decision-making both for onshore and offshore installations and that there was no serious impediment to this from any problems of overall methodology, frequency estimation, consequence modelling or risk criteria.

In contrast to the HSE, the DoEn was not well equipped to operate a regime based on goal-setting regulations and FSA. It had no experts in FSA or fire protection.

A number of recommendations which would have met some of the points on which the DoEn was criticized had been made in the *Burgoyne Report* (Burgoyne, 1980), but had not been implemented.

A19.7 Some Lessons of Piper Alpha

A19.7.1 Some lessons

Lessons from the Piper Alpha disaster are considered in this section with the exception of the recommendations of the report on the offshore safety regime which are considered in Section A19.8. A list of some of the lessons is given in Table A19.2. Many apply particularly to offshore installations, but others are of more general applicability.

Regulatory control of offshore installations

The Piper Alpha disaster exposed weaknesses in the offshore regulatory regime which have already been described. The lessons drawn are seen in the recommendations given in Section A19.8.

Quality of safety management

The *Piper Alpha Report* is critical of the quality of management, and particularly safety management, in the company.

It was not that the company did not put effort into safety. On the contrary, there were numerous meetings and much training on safety. The problem was the quality of these activities.

Many managers had come up through the ranks and had minimal qualifications. The culture tended to be somewhat in-grown and insufficiently self-critical.

These defects manifested themselves in various ways such as in the toleration of poor practices in plant isolation and operation of the PTW system; in the failure to appreciate the ineffectiveness of the audits done; in the failure to address the major hazard problem and to use FSA. The report comments:

> Senior management were too easily satisfied that the PTW system was being operated correctly, relying on the absence of any feedback of problems as indicating that all was well. They failed to provide the training necessary to ensure that an effective PTW system was operated in practice. In the face of a known problem with the deluge system they did not personally become involved in probing the extent of the problem and what should be done to resolve it as soon as possible. They adopted a superficial

> response when issues of safety were raised by others, . . . They failed to ensure that emergency training was being provided as they intended. Platform personnel and management were not prepared for a major emergency as they should have been. (para 14.52)

A crucial weakness was failure to appreciate that absence of feedback to management about problems is almost certainly an indicator not that there are no problems but that there are, and they could be serious. Of one OIM the report states: 'His approach seemed to be, in his own words, "surely that is all you are concerned with about the permit system . . . If the system is working and no problems are identified . . . then you should be reasonably happy with it, surely?" . . . He had been surprised by the number of deficiencies in the operation of the permit system which had been revealed in the Inquiry. He had checked this out and found it to be true.' Of another manager it states that he said 'he knew that the system was monitored on a daily basis by safety personnel. By the lack of feedback he "knew that things were going all right and there was no indication that we had any significant permit to work problems".' (para 14.26)

Safety management system

Onshore the quality of the management and the management system are of prime concern to the HSE in its inspections in general and in the safety case in particular. In submitting a safety case a company will often give extensive documentation on its systems. Nevertheless, in the regulations the formal requirements on management are fairly minimal.

The Inquiry heard evidence in favour of the assurance of safety through the use of quality assurance to standards such as BS 5750 and ISO 9000. It also heard evidence on the need for better qualified management, including a proposed requirement for all OIMs to be graduates.

The concept of a safety management system goes part way towards these insofar as the system itself is based on principles similar to those of quality assurance and covers the question of management quality.

Documentation of plant

The discrepancies in the documentation concerning the rating of the flange on PSV 504 have already been mentioned. The Inquiry in fact heard of a number of other defects in the documentation of the plant. Failure to maintain correct records can have serious consequences.

Fallback states in plant operation

The loss of the working condensate pump on Piper created a situation where operating personnel were under some pressure to start the other pump and avoid a gas plant shutdown with its possible escalation to a total shut-down, loss of power and the need for a 'black start'. In this case the pressure was created partly by the view which an individual took of the probability that the changeover of the main generators from gas to diesel would fail. This illustrates the desirability of ensuring that plants have fallback states short of total shut-down. In this case the problem was in the reliability of changeover, a type of problem which may lie with design or with maintenance.

Permit-to-work systems

The defects in the PTW system have already been described. These defects led directly to a situation where condensate was admitted to a pump from which the PSV had been removed and hence to the disaster. The *Piper Alpha Report* devotes considerable attention to the need for an effective system.

Isolation of plant for maintenance

The *Piper Alpha Report* states that the disaster would not have occurred if A pump had been positively isolated so that condensate could not be admitted. Positive isolation is not achieved by shutting a valve but requires means such as insertion of a slip plate or removal of a pipe section.

Training of contractors' personnel

The proportion of contractors' personnel on an offshore installation can be as high as 70%. The offshore scene therefore exemplifies in extreme form a problem which applies to onshore plants also. This is the need to train contractors' personnel in the company's operating and emergency systems and procedures. Failure to train a contractor's supervisor in the operation of the PTW system on Piper meant that he was unfamiliar with a feature of the system which turned out to be a critical one.

Disabling of protective equipment by explosion itself

The initial explosion on Piper disabled large parts of the protective systems, including power supplies and fire water supplies. It illustrates the importance of taking this factor into account in design and in FSA.

Offshore installations: control of pressure systems for hydrocarbons at high pressure

An offshore production platform contains a large amount of plant containing hydrocarbons at high pressure. The feed to this plant is from the wells, which can sometimes behave in an unpredictable way. The pipelines connected to the platform contain large quantities of hydrocarbon, the high pressure gas pipelines constituting a particularly serious hazard.

There needs therefore to be a comprehensive system for the control of the total pressure system, covering design, fabrication, installation, operation, inspection, maintenance and modification and including control of such features as materials of construction, lifting of loads and so on and personnel need to be trained in the purposes and operation of system.

Offshore installations: limitation of inventory on installation and in its pipelines

The scale of the Piper disaster was due primarily to the large inventory of the three high pressure gas pipelines connected to the platform. The Inquiry heard evidence on the practicalities of reducing the number of gas pipelines connected to a platform. There are many technical problems involved, but the point has been made that such reduction should be a design objective.

The main inventory of hydrocarbons in process on a platform is in the separators. The massive oil pool fire on Piper was fed from the separators. The *Piper Alpha Report* recommends that methods of dumping this inventory be explored.

Evidence was also heard that in some cases the main inventory of hydrocarbons on a platform might be the diesel fuel.

The alternative method of preventing the hydrocarbon inventory from feeding a fire is emergency isolation, which is considered next.

Offshore installations: emergency shut-down system

The ESD system on Piper operated, shut-down ESVs and blew the gas inventory on the platform down to flare.

Nevertheless, the accident drew attention to a number of problems in effecting isolation, some specific to offshore platforms and some more generally applicable.

The Tartan riser ruptured on the outboard side of the ESV so that closure of this valve was of no avail. It is clear that an ESV needs to be located as close to the sea level as practical in order to minimize this risk.

It is possible to go one step further and install a subsea isolation valve, but this is for consideration on a case-by-case basis.

Both types of isolation valve received considerable attention in the Inquiry. However, neither will be effective unless it achieves tight shut-off. The evidence that the main oil line and the Claymore gas line ESVs did not shut-off tightly emphasizes the importance of this feature.

Moreover, in order to be effective the ESD system has to be activated. The fact that on Piper closure of the three gas line ESVs was not part of the platform ESD but had to be effected for each line separately by manual pushbutton, that these buttons were not pushed and that closure only occurred due to loss of power shows that this problem also is not a trivial one.

Offshore installations: fire and explosion protection

An offshore installation is not in general able to call on outside assistance comparable with that available from the fire brigade to an onshore plant. It must be self-reliant.

This implies that both protection against, and mitigation of, fire and explosion on the one hand and fire fighting on the other are of particular importance and that both the hazard assessment and the design and operation of the plant must be of high quality.

Offshore installations: temporary safe refuge

It is clear from the Piper disaster that there needs to be a temporary safe refuge (TSR) where personnel can shelter in an emergency and where the emergency can be controlled and evacuation organized.

This TSR will normally be the accommodation. In most cases it will be on the production platform itself, but it may be on a separate accommodation platform.

The protection of the TSR from ingress of smoke and fumes from outside and from generation of fumes by fires playing on the outside needs careful attention. Measures require to be taken to prevent smoke ingress through doors and through the ventilation system.

Offshore installations: limitation of exposure of personnel

The concept of a TSR is a particular application of the more general principle of limitation of exposure of personnel. The Inquiry also heard evidence of the application of the principle to other aspects such as the location of workshops.

Offshore installations: formal safety assessment

The evidence showed that many companies which operate installations onshore and offshore have formal systems for safety assessment and practise FSA routinely, that FSA has considerable benefits in the design and operation of plant and that it provides a suitable basis for dialogue between the company and the regulatory body.

Offshore installations: safety case

A safety case is a particular form of FSA. The evidence indicated that a safety case is as applicable offshore as onshore and that it is a suitable means for the company to demonstrate to the regulatory body that it has identified the major hazards of its installation and has them under control.

Offshore installations: use of wind tunnel tests and explosion simulations in design

Wind tunnel tests and explosion simulations were used in the Inquiry to investigate the cause of the explosion, but evidence was also heard of their value in platform design.

Wind tunnels may be used to assess the effectiveness of ventilation and of the gas detection system in a module, the wind conditions at the helideck and the movement of smoke from oil pool fires. Explosion simulations may be used to investigate the effect of different module layouts on explosion overpressures and to assess the effectiveness of blast walls.

The explosion and fire phenomena

The Piper disaster drew attention to several important aspects of explosion and fire on offshore installations. These include explosions in semi-confined modules, oil pool fires and jet flames.

Explosions in semi-confined and congested modules are a hazard which assumes particular significance offshore. Although major progress has been made in the last decade in simulating such explosions and developing design methods, this remains an area where further work is needed.

Oil pool fires onshore are relatively well understood, but this does not apply to the behaviour of such a pool fire on an offshore platform. Aspects of some importance are design to prevent accumulation of an oil pool in the first place and the massive smoke plume from such a fire.

Jet flames, including jet flames from risers, are particularly important for offshore platforms. In this case there are available a number of models developed for flares and flames on onshore plant, including pipelines, which can be applied offshore.

Evidence given indicated that in considering the hazard of a jet flame from a riser, the worst case was not necessarily a full bore rupture but a partial rupture, since the latter is sustained for a longer period.

Publication of reports in accident investigation

The Inquiry heard that the company had a policy of severely restricting circulation of accident investigation reports.

Likewise, the DoEn did not make public reports on major offshore accidents. This contrasts markedly with the HSE policy of issuing reports on major accidents, many of which are referred to in this book.

A19.7.2 An accident model

The following outline of a model of the accident highlights the role played by some of the features just mentioned:

	Deficencies in
Initial event: gas explosion	Operational control
Escalation 1: explosion damage	Hazard identification, assessment and management Explosion mitigation
Escalation 2: oil pool fire	Hazard identification, assessment and management Fire mitigation and fire fighting Inter-platform emergency planning
Escalation 3: riser rupture	Hazard identification, assessment and management Fire protection of risers
Escalation 4: accommodation failure	Hazard identification, assessment and management TSR fire and smoke protection Emergency command and control

A19.8 Recommendations on the Offshore Safety Regime

The *Piper Alpha Report* makes recommendations for fundamental changes in the offshore safety regime.

The basis of the recommendations is that the responsibility for safety should lie with the operator of the installation and that nothing in the regime should detract from this.

The offshore regime envisaged in the recommendations is one in which the emphasis is on the operator demonstrating to the regulatory authority the safe design and operation of its installation rather than demonstrating mere compliance with regulations. In this regime the preferred form of regulations is goal-setting rather than prescriptive.

Table A19.3 *Some elements of the safety management system*

Organizational structure
Management personnel standards
Training, for operations and emergencies
Safety assessment
Design procedures
Procedures, for operations, maintenance, modifications and emergencies
Management of safety by contractors in respect of their work
Involvement of the workforce (operator's and contractors') in safety
Accident and incident reporting, investigation and follow-up
Monitoring and auditing of the operation of the system
Systematic re-appraisal of the system in the light of experience of the operator and industry

The recommendations envisage that FSA will play a major role. It may be used to demonstrate compliance with a goal-setting regulation or with the general requirements of the HSWA.

A central feature of the regime proposed is the safety case for the installation. This safety case is broadly similar to that required for onshore installations but there are some important differences. In the offshore safety case it is required that the operator should demonstrate that the installation has a TSR in which the personnel on the installation may shelter while the emergency is brought under control and evacuation organized.

Further, it is recommended that this demonstration should be by QRA. This means that there must be criteria which define the failure of the TSR and criteria for its endurance time and its failure frequency. The criteria may then be met by reducing the frequency of accidental events, by increasing the durability of the TSR or by some combination of these.

The recommendation on the safety case includes a requirement that the operator should demonstrate that it has a safety management system (SMS) to ensure the safe design and operation of the installation. This SMS should draw on quality assurance principles similar to those of BS 5750 and ISO 9000. The elements of the SMS should include those listed in Table A19.3. They include management personnel standards.

Various measures related to hardware were urged at the Inquiry. These included the provision of separate accommodation platforms, the installation of subsea isolation valves and blast walls, the use of freefall lifeboats and purpose-built standby vessels. The report takes the view, however, that in accordance with its basic philosophy such matters should be dealt with as part of the demonstration of safe design and operation.

The report considers that the then current regulatory body, the DoEn, is unsuitable as the body to be charged with implementing the new regime and recommends the transfer of responsibility for offshore safety to the HSE.

These recommendations were accepted immediately by the government and the new regime under the HSE began in April 1991.

Appendix 20

Nuclear Energy

Contents

The energy industries in general have much in common with the process industries in terms of the management, the plant and the hazards. This is true even of the nuclear industry, although this also has a number of unique features. Historically, the nuclear industry has often had to face particular problems before they have impinged on the process industries and has had to devise solutions for them. In consequence, there are a number of areas where work in the nuclear industry is relevant to the process industries.

In this appendix a general account is given of nuclear energy, essentially with reference to those features which are common to, or have impact on, the process industries. Accounts of the accidents at Three Mile Island and at Chernobyl and of the Rasmussen Report are given in Appendices 21, 22 and 23, spectively.

Some topics common to both industries have been dealt with already in other chapters. The account of major hazard control in Chapter 4 covers nuclear hazards. The treatment of management and management systems in Chapter 6 is applicable to nuclear as well as process systems.

General information on nuclear phenomena and on radioactivity is given in *Source Book on Atomic Energy* by Glasstone (1968), *The Effects of Nuclear Weapons* by Glasstone and Dolan (1979), *Nuclear Energy Technology* by Knief (1981) and *A Dictionary of Nuclear Power and Waste Management* by Foo-Sun Lau (1987).

Frequent reference is made in this appendix to two reports issued following the accident at Three Mile Island. These are *The Report of the Presidents Commission on the Accident at Three Mile Island (the Kemeny Report)* (Kemeny, 1979) and *TMI-2 Lessons Learned Task Force Final Report* (*the Task Force Report*) (NRC, 1979d).

Selected references on the nuclear industry are given in Table A20.1.

Table A20.1 *Selected references on nuclear energy. See also Appendix 28, Section B (Nuclear Regulatory Commission)*

A20.1 Radioactivity

Accounts of radioactivity and of ionizing radiations are given by Glasstone (1968), Glasstone and Dolan (1979), Knief (1981), Foo-Sun Lau (1987) and in many texts on physical chemistry such as Moelwyn-Hughes (1961) and W.J. Moore (1963).

Units of radioactivity are defined in Worley and Lewins (1988) (the *First Watt Committee Report*), based on Foo-Sung Lau (1987).

A20.1.1 Types of radiation

There are three main types of radioactive particle or ray: (1) α-particles, (2) β-rays or particles and (3) γ- and X-rays.

α-particles are helium nuclei, or protons. Their mass is relatively large and their range correspondingly short. An air gap of about 8 cm or a sheet of paper may suffice to stop them. Generally, they present little external radiation hazard, but they are dangerous if they get inside the body.

β-rays, or particles, are electrons. They have a much smaller mass and greater penetrating power. Their range in air is about 10 m, but they are usually stopped by a few millimetres of solid material.

γ- and X-rays are electromagnetic radiations, or photons, which differ from each other only in respect of source and wavelength. They have a range of several hundred metres, but can be stopped by a few millimetres of lead or 0.5–1 m of concrete.

Both β-rays and γ- and X-rays constitute an external radiation hazard.

Ionizing radiation may be classified as direct or indirect. The former consists of particles and thus includes α-particles (protons) and β-particles (negatively charged electrons) and positrons (positively charged electrons), while the latter includes γ- and X-rays (both photons) and also neutrons.

A20.1.2 Units of radiation

The units of activity of a radioactive source are bequerels (Bq) and curies (Ci)

$$1\ \text{Bq} = 1\ \text{disintegration/s}$$

$$1\ \text{Ci} = 3.7 \times 10^{10}\ \text{Bq}$$

Another unit of source strength is the roentgen (R), which defines the ionization effect of γ- and X-rays.

1 R produces in 1 cm^3 air ions carrying a charge of 1 electrostatic unit (esu)

For γ- and X-ray radiation 1 R is equivalent to the absorption of 87 erg/g of air. However, for other types of radiation and targets the equivalences are significantly different.

Units of absorbed dose are rads and grays (Gy), the latter being the modern unit.

$$1\ \text{rad} = 100\ \text{erg/g} = 0.01\ \text{J/kg}$$

$$1\ \text{Gy} = 1\ \text{J/kg} = 100\ \text{rad}$$

The effect on man of a given absorbed dose D is a function of the type of radiation, for which a quality factor Q is defined. The value of Q is unity for γ- and X-rays and electrons, but has other values for other types of radiation. The value of Q for α-particles is 20. The quality factor is also referred to as the relative biological effectiveness (RBE).

The dose equivalent H is the product of the absorbed dose and the quality factor:

$$H = D \times Q \qquad \text{[A20.1.1]}$$

Units of effective dose, or dose equivalent, are rems and sieverts (Sv), the latter being the modern unit

$$1\ \text{rem} = 1\ \text{rad} \times \text{Q}$$

$$1\ \text{Sv} = 1\ \text{Gy} \times \text{Q}$$

$$1\ \text{Sv} = 100\ \text{rem}$$

Thus the roentgen is the unit of total dose, the rad or gray that of absorbed dose and the rem or sievert that of effective dose.

In the context of discussion of biological effects effective dose is frequently referred to simply as dose.

A20.1.3 Radioactive decay

Specific Activity and Half Life

The basic equation for radioactive decay is

$$-\frac{\mathrm{d}n}{\mathrm{d}t} = \lambda n \qquad \text{[A20.1.2]}$$

where n is the number of radioactive atoms, t time and λ the radioactive decay constant (s^{-1}). Then from Equation A20.1.2

$$\frac{n}{n_0} = \exp(-\lambda t) \qquad \text{[A20.1.3]}$$

where n_0 is the number of radioactive atoms at arbitrary time zero. The half-life τ is defined by the relations

$$\frac{n}{n_0} = \frac{1}{2} = \exp(-\lambda\tau) \qquad [A20.1.4]$$

$$\tau = \ln 2/\lambda = 0.693/\lambda \qquad [A20.1.5]$$

But

$$n_0 = N_0/M_a \qquad [A20.1.6]$$

where M_a is the atomic weight and N_0 is Avogadro's constant ($= 6.024 \times 10^{23}$). Then from Equations A20.1.2, A20.1.3 and A20.1.6 at arbitrary time $t = 0$ ($n = n_0$)

$$-\frac{dn}{dt} = \lambda \frac{N_0}{M_a} = \frac{\ln 2}{\tau} \frac{N_0}{M_a} \qquad [A20.1.7]$$

Energy release

The release of energy during radioactive decay is governed by the relation of Einstein

$$E = mc^2 \qquad [A20.1.8]$$

where c is the velocity of light, E the energy release and m the mass.

The energy may be calculated from the decay equation by determining the difference in mass of the two sides. An atomic mass unit (amu) is equivalent to 931 MeV.

For example, for the decay of polonium 210 to lead 206 and helium nucleus, or α-particle, the decay equation is

$${}_{84}\mathrm{Po}^{210} \rightarrow {}_{82}\mathrm{Pb}^{206} + {}_{2}\mathrm{He}^{4}$$

and the atomic mass balance is

		Atomic mass
LHS	${}_{84}\mathrm{Po}^{210}$	210.049
RHS	${}_{82}\mathrm{Pb}^{206}$	206.034
	${}_{2}\mathrm{He}^{4}$	4.004
Total RHS		210.038
Mass loss		0.011

Energy = 931 × 0.011 = 10.2 MeV

A20.1.4 Radioactivity health effects

An account of health effects from radiation is given in *Living with Radiation* by the National Radiation Protection Board (NRPB) (1989). An account in the specific context of Chernobyl is given by the Watt Committee on Energy (1991).

Potential health effects of radiation at relatively low doses are short term: (1) birth defects from radiation received by the foetus; (2) thyroid cancers from radioactive iodine; from 3 years onwards: (3) leukaemia; over a period 5–40 years: (4) cancers; and over a generation: (5) genetic effects.

Recommendations for radiation protection standards are given in *Radiological Protection Bulletin 141 1993* by the NRPB (1993). Details are given in Chapter 25.

A20.2 Nuclear Industry

A20.2.1 Nuclear industry regulation

Public control of the nuclear industry is discussed in Chapter 4. In the United Kingdom the regulatory body is the Nuclear Installations Inspectorate (NII), which is part of the HSE. In the United States of America it changed in the mid-1970s from the Atomic Energy Commission (AEC) to the Nuclear Regulatory Commission (NRC).

A20.2.2 Nuclear industry advisory committees

In the United Kingdom there is a standing committee, the Advisory Committee on the Safety of Nuclear Installations (ACSNI) which advises on nuclear safety. In the United States of America there is an Advisory Committee on Reactor Safety (ACRS).

Advice on radiological protection in the United Kingdom is the responsibility of the National Radiological Protection Board (NRPB).

A20.2.3 International bodies

Bodies operating at the international level include the International Atomic Energy Agency (IAEA) in Vienna and the International Committee on Radiological Protection (ICRP). The IAEA was set up in 1957 as an intergovernmental organization linked to the UN.

A20.2.4 Nuclear industry research

Work for the nuclear industry is a main source of support for a number of major research laboratories and organizations whose output is also of interest to the process industries. In the United Kingdom these include the UK Atomic Energy Authority (UKAEA), which operates laboratories at Harwell. The Systems Reliability Directorate (SRD) is part of the UKAEA.

In the United States of America major laboratories with a nuclear interest include the Argonne National Laboratory (ANL), Brookhaven National Laboratory (BNL), Electric Power Research Institute (EPRI), Lawrence Livermore National Laboratory (LLNL), Oak Ridge National Laboratory (ORNL) and Sandia Laboratories (SL).

A20.2.5 Nuclear industry accidents

Early perceptions of the hazard from the nuclear industry were coloured by the image of an explosion from a nuclear weapon. A major accident in the nuclear industry, a core meltdown, is quite different. There would not be the initial intense blast and radiation effects, but rather a dispersion of radioactive material at the site and from the site by the wind. Such an accident occurred at Chernobyl.

A20.2.6 Nuclear industry debate

Virtually from its inception the nuclear industry has been the subject of debate. Some principal critiques are *Nuclear Power* by Patterson (1976), *Soft Energy Paths* by Lovins (1977), *The Risks of Nuclear Power Reactors* by the Union of Concerned Scientists (UCS) (1977), *Nuclear or Not*? by Foley and van Buren (1978), *Cover-up* by Grossman (1980), *The Fast Breeder Reactor* by Sweet (1980), *The PWR Decision* by Cannell and Chudleigh (1984), *Going Critical* by Patterson (1985) and *Nuclear Politics* by T. Hall (1986).

A20.3 Nuclear Reactors

Accounts of nuclear reactor systems include *Nuclear Reactor Control and Instrumentation* by J.H. Bowen and Masters

(1959), *Nuclear Reactor Engineering* by Glasstone and Sesonke (1962), *Nuclear Energy Technology* by Knief (1981), *Nuclear Power Technology* by W. Marshall (1984), *The Elements of Nuclear Power* by D.J. Bennett and Thompson (1989) and *The Technology of Nuclear Reactor Safety* by T. Thompson and Beckerley (1989).

Treatments by the HSE include PWR (HSE, 1979d), *Safety Assessment Principles for Nuclear Reactors* (HSE, 1979f) and *Sizewell B* (HSE, 1982b).

A20.3.1 Nuclear reactor types

Some principal types of nuclear reactor are

(1) Gas-cooled reactors:
    (a) Magnox reactor;
    (b) Advanced gas-cooled reactor (AGR);
    (c) High temperature gas-cooled reactor (HTGR);
(2) Light water reactors (LWRs):
    (a) Pressurized water reactor (PWR);
    (b) Boiling water reactor (BWR);
(3) Heavy water reactors:
    (a) CANDU reactor;
    (b) Steam generating heavy water reactor (SGHWR);
(4) Fast breeder reactors.

Accounts of reactor types are given in *Nuclear Power Reactors* by the UKAEA (1987) and by Patterson (1976) and Lewins (1988).

In the United Kingdom the first reactors were the gas-cooled Magnox reactors. The next generation were the AGRs reactors. The first pressurized water reactor came much later, at Sizewell B.

Elsewhere, notably the United States of America and France, the vast majority of reactors installed have been PWRs.

A20.3.2 Reactor design features

In a nuclear reactor energy is released by a chain reaction involving neutrons. The reaction is sustained by those neutrons which are absorbed. Slower neutrons are absorbed in larger proportion than faster ones. Use is made, therefore, of a 'moderator' to slow down the neutrons. In some designs the moderator is graphite, for example, the Magnox reactor, while in others it is water, for example, the PWR.

The power output of the reactor is controlled by movement of control rods, containing materials which are strong absorbers of neutrons, and the reactor is shut down by their full insertion. Emergency shut down, or scram, is effected by dropping in the rods.

Even when shut down the reactor has a certain output of heat, due to radioactivity in the core. This decay heat needs to be removed if the core is not to overheat. The removal of the decay heat is one of the main problems which have to be handled in reactor design.

The reactor core is cooled by a coolant which in the AGR is carbon dioxide and in the PWR is water.

A20.3.3 Advanced gas-cooled reactors

The underlying concept of the AGR is that if forced convection circulation of the gas coolant is lost, natural convection will still effect a degree of cooling. To this extent, the reactor is an application of inherently safer design.

A20.3.4 Pressurized water reactors

The majority of nuclear reactors installed world-wide are PWRs. In the PWR design the core is cooled by water which also doubles as the moderator.

A PWR is provided with multiple systems to inject cooling water into the reactor to keep the core cool and with numerous protective systems to ensure the operation of this backup cooling. The reactor is vulnerable in the event of the failure of these instrument and cooling systems. On a PWR an emergency can escalate within a relatively short time scale.

In a PWR the fuel is inside three sets of containment. The first is the fuel rods. The second is the reactor pressure vessel (RPV) in which the fuel rods are held. The third is the containment building which encloses the reactor vessel.

The reactor is vulnerable to loss of coolant and much attention has been focused on the large loss of coolant (LOCA) accident.

A20.3.5 Inherently safer design

In view of the nature of the hazard from a nuclear reactor, there is interest in inherently safer design. Mention has already been made of the inherent safety aspects of the AGR.

A review of approaches to inherently safer design of nuclear reactors is given in *Proposed and Existing Passive and Safety-related Structures, Systems and Components (Building Blocks) for Advanced Light Water Reactors* by Forsberg *et al.* (1989).

Some examples are discussed by Kletz (1988h). The HTGR is a small reactor cooled by high pressure helium. The reactor is designed to withstand a high temperature and to have an adequate heat loss by radiation and natural convection if the coolant should fail. The Swedish process-inherent ultimate safety (PIUS) reactor is a water-cooled reactor immersed in boric acid solution, so that if the coolant pumps fail this solution is drawn through the core by natural convection.

Another aspect of inherent safety is the reliability of the overall system for the control and protection of the reactor, which includes both the automatic control and protection and the process operator. As already mentioned, a PWR is vulnerable to equipment failure in the instrument and coolant systems which protect it. It is therefore vulnerable also to operator actions which render this protection ineffective.

This feature is discussed by Franklin (1986) in these terms:

> When operators are subject to conditions of extreme emergency arising from a combination of unforeseen circumstances they will react in ways which lead to a high risk of promoting accidents rather than diminishing them. This is materially increased if operators are aware of the very small time margins that are available to them.

A20.4 Nuclear System Reliability

A20.4.1 Pressure systems

The integrity of the pressure system is critical to the safety of a nuclear reactor such as the PWR. Much attention has been therefore focused on the potential for pressure vessel failure.

Pressure vessel failure is considered in the *Rasmussen Report*. It is also discussed by Bridenbaugh, Hubbard and Minor (1976) and Cottrell (1977).

It was a principal issue at the Sizewell B inquiry, and an account is given in Appendix 26.

The treatment given in Chapter 12 of failure rates of pressure vessels draws heavily on estimates made with nuclear applications in mind.

A20.4.2 Protective systems

From the start the nuclear industry made extensive use of instrumentation, and particularly of instrumented protective systems. Accounts of this work are given in *Reliability Assessment of Protective Systems for Nuclear Installations* by Eames (1965 AHSB(S) R99) and *Safety Assessment with Reference to Automatic Protective Systems for Nuclear Reactors* by A.E. Green and Bourne (1966 AHSB(S) R136).

This work led to interest in reliability technologies, including fault trees and dependent failure. Since it was necessary to have a target to aim for in design of such protective systems, this also prompted the development of risk criteria.

A20.4.3 Reliability engineering

The nuclear industry joined the defence and aerospace industries in developing reliability techniques. A treatment of reliability engineering from the viewpoint of the nuclear industry and with special reference to protective systems, is *Reliability Technology* by A.E. Green and Bourne (1972).

A20.4.4 Failure and event databases

The practice of reliability engineering created the need for failure and event databases. This is illustrated by the development of the database of the UKAEA Systems Reliability Service (SRS) (Ablitt, 1973 SRS/GR/14). The development of this database is described in Appendix 14.

A20.4.5 Fault trees

The need to identify failure paths and to estimate failure frequencies for systems with multiple layers of protection has led in the nuclear industry to extensive use of fault tree analysis. It is the basic method used for frequency estimation in the *Rasmussen Report*. The technique is described in *Reliability and Fault Tree Analysis* by Barlow, Fussel and Singpurwalla (1975) and in *Fault Tree Handbook* by Vesely *et al.* (1981).

Associated with this work are the fault tree analysis computer codes PREP and KITT (Vesely and Narum, 1970).

A20.4.6 Event trees

Likewise, the nuclear industry has made much use of event trees, both to identify and quantify the effects of certain failures, such as those of the power supply, and the outcomes of a release to atmosphere.

A20.4.7 Dependent failures

Nuclear reactors rely on extensive protective systems to give a very high degree of reliability, and it is characteristic of such systems that they are liable to be defeated by dependent failure. In some cases different assumptions about dependent failure can result in a dramatic increase in the estimated frequency of an accident. The nuclear industry has therefore put much effort into the study of this problem.

The problem of dependent failure bulks large in the analyses in the Rasmussen Report and in the critiques of that report.

An account is given in *Defences against Common-mode Failures in Redundant Systems* by Bourne *et al.* (1981 SRD R196).

A20.5 Nuclear Hazard Assessment

A20.5.1 Probabilistic risk assessment

The nuclear industry has for long made use of probabilistic risk assessment (PRA), or probabilistic safety assessment (PSA), as a means of ensuring that its hazards are identified and under control and as a basis for dialogue on this with the regulatory authority. Guidance is given in *PRA Procedures Guide* by the NRC (1982). A more recent treatment is *Procedures for Conducting Probabilistic Safety Assessment of Nuclear Power Plant* by the IAEA (1992).

The *Rasmussen Report*, described in Appendix 23, is one well known generic PRA. Another is the *Deutsche Risikostudie Kernkraftwerke* by the Technische Uberwachungsverein (TUV) (1979).

A20.5.2 Accident sequences and scenarios

In a nuclear PRA considerable effort is devoted to the treatment of the accident sequences, or scenarios.

Thus a large proportion of the IAEA document just referred to is devoted to procedures for the identification of accident initiators and of accident sequences, for the classification of accident sequences into plant damage states and for the determination of the frequency of the accident sequences.

A20.5.3 Rare events

There are a number of natural and man-made threats which may hazard a nuclear plant. Examples of these two types of event are, respectively, an earthquake and an aircraft crash. Such events, their consequences and frequency, have therefore been the subject of much study by the nuclear industry.

A20.5.4 Explosions

One type of the event which may put a nuclear plant at risk is an explosion. The industry has examined various kinds of explosion, including vapour cloud explosions, and certain types of particular interest to it such as steam explosions and hydrogen explosions.

A20.5.5 Hydrogen explosions

The fuel elements in the reactor core are held in metal cladding tubes. At high temperatures the zirconium metal used for this cladding can react with steam to produce hydrogen, with the risk of a hydrogen explosion.

A20.5.6 Missiles

Studies of some relevance to process plants are those on missiles such as the work reported by Baum (1984, 1991).

A20.5.7 Earthquakes

Of rare natural events, the earthquake hazard bulks large both in plant design and in risk assessment. The nuclear regulator has put much effort into defining the type of earthquake which the plant should be required to withstand. Guidance is given in *Design Response Spectra for Seismic Design of Nuclear Power Plants* by the NRC (1973).

Then, given such a design earthquake, it is possible to specify equipment to withstand it, as described below.

A20.5.8 Expert judgement

Where hard information is lacking, resort may be had to the use of expert judgement. Thus expert judgement may be used to obtain estimates of failure and event rates. It may also be applied to other aspects such as the formulation of accident sequences. Guidance on this approach is given in *Eliciting and Analysing Expert Judgement: a Practical Guide* by M.A. Meyer and Booker (1990).

A20.5.9 Computer error

A modern nuclear power station operates under computer control. The control computer, both hardware and software, is therefore a safety critical system.

The quality assurance of the computer software is a particularly intractable problem. An account of this aspect of the Sizewell B computer system is given by Hunns and Wainwright (1991).

A20.5.10 Human error

The conduct of PRA for nuclear plants has led naturally to a requirement for methods of handling the human aspects, particularly in fault trees and in event trees. An overall methodology for this problem is described in *Handbook of Human Reliability Analysis with Emphasis on Nuclear Power Plant Applications* by Swain and Guttman (1983). A method of estimating error probabilities is addressed in *SLIM-MAUD: an Approach to Assessing Human Error Probabilities using Structured Expert Judgement* by Embrey *et al.* (1984).

Also relevant is the ACSNI Study Group on Human Factors *Second Report: Human Reliability Assessment – a Critical Overview* (ACSNI, 1991).

A20.5.11 Source terms

Each accident scenario needs to be associated with a defined source term, so that the dispersion of radioactive materials may be modelled.

A20.5.12 Emission models

The nuclear industry was one of the first to develop a sustained interest in two-phase flow, both flow within the plant and flow of leaks from it. An example of work from a nuclear background is *Two-Phase Flow and Heat Transfer* by Butterworth and Hewitt (1977).

A20.5.13 Gas dispersion models

Much of the work on gas dispersion modelling has been in support of work on the consequences of a nuclear accident. This is illustrated by one of the early texts, *Meteorology and Atomic Energy* 1968 by Slade (1968).

A20.5.14 Severe accident risk

A focus to work on PRA has latterly been provided by the Severe Accident Risk study, for which the basic document is NUREG-1150 *Reactor Risk Reference Document* of the NRC (1987).

A20.5.15 Risk criteria

The quantification of risks from nuclear reactors has necessarily led to the need for risk criteria by which to judge these risks. Some of the first risk comparisons were those given in the *Rasmussen Report*.

Since then, there has been a wide-ranging debate of risk criteria for man-made hazards of all kinds. Nuclear risk criteria emerging from this are given in *The Tolerability of Risk from Nuclear Power Stations* by the HSE (1988b), and associated comments (HSE, 1988a).

A20.6 Nuclear Pressure Systems

A20.6.1 Quality assurance

All aspects of the design and operation of nuclear power plant need to be carried out to high standards. There has to be, therefore, a system of quality assurance to ensure that these standards are met.

This aspect is described in NUREG-1055 *Improving Quality and the Assurance of Quality in the Design and Construction of Commercial Nuclear Power Plants* (NRC, 1984).

A20.6.2 Inspection

High-quality inspection is an essential part of the nuclear industry's armoury. It has a special interest in non-invasive techniques of monitoring and inspection. These include acoustic emission monitoring, ultrasonics and leak detection methods.

Methods of leak detection are described in NUREG/ CR-4813 *Assessment of Leak Detection Systems for LWRs* (NRC, 1987).

The industry has also developed risk-based inspection. An account is given in NUREG/CR-5371 *Development and Use of Risk-based Inspection Guides* (NRC, 1989).

A20.6.3 Fracture mechanics

One of the most powerful inspection techniques for pressure systems is fracture mechanics and the nuclear industry has been in the van in developing such methods. They include the CEGB R6 system described in R/H/R6 *Assessment of the Integrity of Structures Containing Defects* by Milne *et al.* (1986).

A20.6.4 Seismic qualification

One of the principal external hazards to which a nuclear plant is vulnerable is an earthquake. There is therefore a requirement that equipment crucial to safe operation be able to withstand an earthquake of specified intensity. This is implemented by a system of seismic qualification of equipment. An account is given in NUREG-1030 *Seismic Qualification of Equipment in Operating Nuclear Power Plants* by the NRC (1987).

A20.6.5 Ageing

Another aspect which the nuclear industry has explored in some detail is ageing of equipment, and residual, or remanent, life assessment.

An account of basic principles is given in NUREG/ CR-5314 Life Assessment Procedure for Major LWR Components (NRC, 1990). There are studies on specific equipment such as electric motors, diesel generators, instrument air systems, motor operated valves, etc.

A20.7 Nuclear Reactor Operation

The *Kemeny Report* and, even more, the *Task Force Report* on TMI contain numerous recommendations on nuclear reactor operation, particularly on the design of display and alarm systems and of control rooms generally, operating and emergency procedures, and operator training.

A20.7.1 Human factors

A considerable effort is made to apply human factors on nuclear power plants, a practice reinforced by the *Kemeny Report's* emphasis on people-related problems.

Some typical titles which illustrate the application of human factors on nuclear power plants are as follows: NUREG/CR-3331 *A Methodology for Allocating Nuclear Power Plant Control Functions to Human or Automatic Control* (NRC, 1983); NUREG/CR-3371 *Task Analysis of Nuclear Power Plant Control Room Crews* (NRC, 1984); and NUREG-1122 *Knowledges and Abilities Catalog for Nuclear Power Plant Operators* (NRC, 1987).

Three reports on human factors in nuclear power plant operation have been issued by the ACSNI Study Group on Human Factors. Reference has already been made to the second report, on human reliability assessment (ACSNI, 1991). The other two are First Report on Training and Related Matters (ACSNI, 1990) and Third Report: Organising for Safety (ACSNI, 1993).

A20.7.2 Process operator

The problems, and modelling, of the process operator have been the subject of extensive studies, notably the work described in *Information Processing and Man–Machine Interaction* by Rasmussen (1986).

A20.7.3 Display and alarm systems

Early developments in computer aids for the process operator were the alarm analysis systems developed at Wylfa and Oldbury nuclear power stations, described by Welbourne (1965) and Patterson (1968), respectively. The purpose of these systems is to assist the operator in interpreting the large number of alarms which tend to come up in a plant emergency.

One of the perceived problems at TMI was the difficulty experienced by operators in assessing the safety status of the plant. A recommendation of the Task Force Report was that every reactor should have a plant safety status display.

TMI also illustrated the alarm interpretation problem just mentioned and the report recommended that the feasibility be explored of developing a suitable aid, which it termed a disturbance analysis system (DAS).

A20.7.4 Control room design

A large proportion of the studies conducted on control rooms have been in the nuclear industry, and these have contributed to the development of understanding of human factors and human error.

In the aftermath of TMI control room design in general was also an issue. This illustrated in NUREG-0700 *Guidelines for Control Room Design Reviews* (NRC, 1981).

A set of studies of the Sizewell B control room are described by Ainsworth and Pendlebury (1994), Umbers (1994) and Whitfield (1994).

A20.7.5 Operating procedures

In the operation of nuclear power plants particular emphasis is placed on written operating procedures and on the training of operators in these. An account is given in NUREG/CR-3968 *Study of Operating Procedures in Nuclear Power Plants* (NRC, 1987).

A20.7.6 Emergency procedures

Operating procedures for dealing with an emergency assume particular importance on nuclear power plants. The *Kemeny Report* and the *Task Force Report* make recommendations on the emergency procedures.

Such procedures are the subject of NUREG/CR-0899 *Guidelines for the Preparation of Emergency Operating Procedures* (NRC, 1982) and NUREG/CR-3177 *Methods for Review and Evaluation of Emergency Procedure Guidelines* (NRC, 1983).

A20.7.7 Operator training

Process operators on nuclear power plants undergo extensive training, for which the industry makes appreciable use of simulators.

The need for such training is a principal theme of both the *Kemeny Report* and of the *Task Force Report* on TMI. It is also the subject of the first report of the Study Group on Human Factors of the ACSNI (1990). Simulator training is treated in NUREG/CR-3725 *Nuclear Power Plant Simulators for Operator Licensing and Training* (NRC, 1984) and numerous other reports.

A20.8 Nuclear Emergency Planning

An emergency plan, covering both on-site and off-site aspects, is an integral part of the arrangements at a nuclear power plant.

A20.8.1 Accident management plans

There has been growing emphasis on the need to plan for and to manage an emergency.

Relevant work is that described in NUREG/CR *Management of Severe Accidents* by the (NRC, 1985) and NUREG/CR-5543 *A Systematic Process for Developing and Assessing Accident Management Plans* by the NRC (1991).

A further account is given by Ang (1992).

A20.8.2 Off-site emergency plans

Off-site emergency planning has been a feature of the nuclear industry from its earliest days. An account is given in *Emergency Plans for Civil Nuclear Installations* by the HSE (1986b).

A20.9 Nuclear Incident Reporting

In most regulatory regimes the nuclear industry is required to report to the regulator the occurrence of specified types of incidents.

A20.9.1 Licensee Event Reports

In the United States of America the system is that described in the NUREG/CR-2000 *Licensee Event Report* (LER) compilation.

A20.9.2 Precursors to severe accidents

The LERs record some events which are of such a nature that they could well have escalated into more severe events, even though in the particular case this has not occurred. These events are precursors of more serious incidents and serve as warnings. Periodic analyses are made of such precursors such as NUREG/CR-4674 *Precursors to Potential Severe Core Damage Accidents 1990: Status Report* by the NRC (1991).

A20.10 Nuclear Incidents

There have been a number of incidents on nuclear plants which are instructive for the process industries also. In addition to TMI and Chernobyl, they include Windscale and Browns Ferry.

Accounts of incidents include those in *Nuclear Power* by Patterson (1976), *The Nuggett File* by the UCS (1979) and *Nuclear Lessons* by Curtis *et al.* (1980); later incidents are covered by May (1989).

A20.10.1 Radioactive sources

Although the incidents of prime interest here are those involving nuclear plant, other nuclear sources should not be neglected. The following case, believed to be the worst of it kind to date, illustrates the hazard from equipment containing a radioactive source.

In 1985 in Goiania, Brazil, a radiotherapy institute moved premises, leaving behind a unit containing a caesium-137 source in a stainless steel container and without notifying the licensing authorities. Subsequently the building was partially demolished. Some 2 years after the institute's departure, on 13 September 1987, two men entered and tried to dismantle the machine for scrap, one taking home the steel cylinder; both fell ill. However, some 5 days later one broke open the steel cylinder and the caesium spilled out. A train of events ensued which resulted in 249 people being exposed to radiation, of whom four died.

A20.10.2 Military reactors and weapons plants

Hanford, the Green Run, 1949

On 2 December 1949 at Hanford, Washington State, there occurred one of a series of releases from an installation of eight nuclear reactors producing plutonium for the Manhattan Project. This was the Green Run, an experiment conducted to investigate monitoring methods which would be useful in intelligence work on the nuclear capabilities of other countries. The release formed a plume 200 miles × 40 miles in dead calm conditions and involved 20,000 Ci of xenon and 7780 Ci of iodine-131.

Rocky Flats, Colorado, 1957

On 11 September 1957 at Rocky Flats, Colorado, a fire occurred in a glove box at an atomic weapons plant. Plutonium shavings ignited spontaneously, workers tried to put the fire out and explosions occurred which blew out the ventilation filters. For half a day there was a release of plutonium contaminated smoke. On 11 May 1969 there occurred another glove box fire. All new weapons production was shut down for 6 months.

Idaho Falls, Idaho, 1961

On 3 January 1961 at Idaho Falls, Idaho, an incident occurred on a prototype military nuclear power plant, the Stationary Low Power Reactor SL-1, one of 17 reactors at the AECs National Reactor Test Station (NRTS). The reactor was shut down and control rods had been disconnected to install additional instrumentation. The emergency started with the sounding of alarms. As it developed, three men working on the control rods were found to be missing. One was discovered dead, pinned to the ceiling by a control rod, another was also dead and the third died soon after. The precise sequence of events is uncertain. One explanation given is that the central control rod was partially withdrawn and there was a power surge, generating steam which lifted the lid of the pressure vessel, causing it to rise 9 ft and then drop back.

A20.10.3 Windscale

Accounts of the Windscale incident are given in *Windscale Fallout* by Breach (1978) and *Windscale 1957* by L. Arnold (1992) and by May (1989).

On 10 October 1957 at Windscale, United Kingdom, an incident occurred which led to a serious radioactive release. The installation consisted of two simple air-cooled, graphite-moderated, atomic piles used for the production of plutonium. The graphite was subject to deformation and build-up of energy due to neutron bombardment, the so-called Wigner effect. A procedure had been established to release the Wigner energy by turning off the fans, making the pile critical and letting heat build up. On 7 October 1957, this procedure had been followed, but it appeared that not all the Wigner energy had been released, so the pile was heated up again. The sensors then showed an abnormal temperature rise and the power was reduced. By 9 October conditions seemed normal except that there was a hot spot. However, on 10 October a rise in radioactivity was detected at the filters in the chimney. An attempt was made to inspect the core using a remote scanner, which jammed. Staff removed a charge plug and looked in. All the fuel channels which they could see were on fire and a fuel cartridge had burst. The air movement caused by the fans was now fanning the blaze. Despite fears that it might lead to a hydrogen–oxygen explosion, the decision was taken to use water to put out the fire, which it did. As a result of the incident, workers on the site were exposed to radiation and milk from cattle in the area had to be discarded. The release was mitigated by the presence of the filters, installed at the insistence of Sir John Cockcroft, prominent at the top of the chimney, and known locally as 'Cockcroffs Folly'. The piles were decommissioned and set in concrete.

A20.10.4 Civil nuclear reactors and reprocessing plants

Chalk River, Ontario, 1957

On 12 December 1957 at Chalk River, Ontario, there was a loss of control on a nuclear reactor leading to damage of the core so that it had to be removed and buried. In outline the initial sequence of events was as follows. Outside the control room, a supervisor found that an operator was opening valves which caused the control rods to withdraw. He immediately set about shutting the valves, but some of the rods did not drop back. He telephoned the operator in the control room, intending to ask him to push a button which would drop control rods in, but by a slip of the tongue actually referred to a button which would withdraw rods. In order to comply, the operator moved away from the phone so that the supervisor temporarily lost touch with him. The operator in the control room soon recognized from the rising reactor temperature that there was something wrong and pressed the scram button, but events had been set in train which led to core damage.

Detroit, Michigan, 1966

On 5 October 1966 near Detroit, Michigan, the Enrico Fermi reactor experienced an incident. The reactor was the first commercial fast breeder reactor in the United States of America. It was being started up for a series of tests when abnormalities were observed and some of the control rods were found not to be in their expected positions. Tests on the sodium coolant showed it to be contaminated, suggesting that part of the fuel core had melted, but the cause was unknown. The authorities were alerted and went on standby for evacuation. Subsequent investigation found that separation had occurred of parts from a steel cone at the bottom of the vessel, installed so that in a meltdown the fuel would spread out and not reach critical mass. In a last-minute modification, zirconium plates had been put onto the cone. One plate had worked loose, had been forced into the core by the sodium coolant and had blocked coolant flow to two of the fuel assemblies.

An account of this incident is given in *We Almost Lost Detroit* by Fuller (1984).

Browns Ferry, Alabama, 1975

Prior to TMI one of the US incidents which received particular attention was that on 22 March 1975 at Browns Ferry. Accounts are given in the *Rasmussen Report* and in *Browns Ferry: the Regulatory Failure* by Ford, Kendall and Tye (1976). The incident is described in Appendix 23.

Beloyarsk, USSR, 1978

On 30–31 December 1978 at Beloyarsk, USSR, there occurred an incident which until Chernobyl was the most serious in the nuclear industry. The complex was 50 km from Sverdlovsk and housed two RMBK reactors and a BM600 fast breeder reactor. A serious fire broke out in the machine hall, causing steel girders and the concrete roof to collapse, opening up a huge hole above No. 2 Generator and disabling the fire protection system. Emergency procedures called for both RMBK reactors to be shut down. But as it was close to $-50°C$ outside, it was feared the reactor cooling systems would freeze and the cores would overheat. Attempts were made to keep No. 1 Reactor and its turbine running, but despite the fire the turbine froze. There followed an extended emergency which eventually, with the arrival of fire fighters from outside, was brought under control.

Cap la Hague, France, 1981

On 6 January 1981 at Cap la Hague, Normandy, France, in a nuclear fuel reprocessing facility there occurred the most serious of a series of incidents. Fire broke out in a spent fuel dry waste silo. Ignition occurred in cotton waste, soaked in solvent and in contact with uranium and magnesium. The cotton waste had been used in a decontamination operation there several weeks earlier. The fire was attacked first by water, which formed steam, and then by liquid nitrogen. Radioactivity was released inside and outside the plant.

New York State, 1982

On 25 January 1982 in New York State the Ginna reactor experienced tube rupture, due to corrosion, in the steam generator, causing contamination of the secondary, clean steam circuit by the radioactive water from the primary water circuit cooling the core. High pressure in the steam circuit caused a pressure relief valve to open, initially in 5 min bursts and then by sticking open for 50 min. Another PRV on the primary circuit was deliberately opened to reduce the pressure in that circuit but also stuck open. A steam bubble formed, but it proved possible to correct it by pumping in more water.

Frankfurt, FRG, 1987

On 16–17 December 1987 at Frankfurt, FRG, the Biblis A nuclear reactor experienced an incident involving the low pressure injection (LPI) system. It was a requirement that this system remain isolated to prevent (1) leakage of primary coolant out through it and (2) overpressure of the system itself by the primary coolant. During start up the main valve TH22 S006 on the pipe between the LPI system and the primary circuit had been left open; there were also two secondary valves on the line. The status of the main valve was shown by a red light on the control panel, but the operators assumed that the fault was on the light itself. There were two changes of shift before it was realized that valve TH22 S006 was open. The operators took 2 h to decide on a plant shut down and then 10 min later changed their minds and tried an alternative, and hazardous, procedure. They decided to initiate flow through valve TH22 S006, expecting that the valve would then be shut by its trip system. They controlled the flow by cracking open one of the secondary valves and primary coolant started to escape, but valve TH22 S0006 did not shut, and after a few seconds they desisted. The operators then shut the reactor down.

A20.11 Notation

c	velocity of light
D	absorbed dose (Sv)
E	energy
H	dose equivalent (Sv)
m	mass
M_a	atomic weight
n	number of radioactive atoms
n_0	number of radioactive atoms at time zero
N_0	Avogadro's number
Q	quality factor
t	time
λ	radioactive decay constant (s^{-1})
τ	half-life (s)

Appendix 21

Three Mile Island

Contents

At 4.00 on 28 March 1979, a transient occurred on Reactor No. 2 at Three Mile Island, near Harrisburg, Pennsylvania. A turbine tripped and caused a plant upset. The operators tried to restore conditions, but, misinterpreting the instrument signals, misjudged the situation and took actions which resulted in the loss of much of the water in the reactor and the partial uncovering of the core. Radioactivity escaped into the containment building. Site and general emergencies were declared.

The accident at Three Mile Island (TMI) (also referred to initially as Harrisburg) was the most serious accident which had occurred in the US nuclear industry.

The President set up a commission to investigate the accident. Their work is described in *The Report of the Presidents Commission on the Accident at Three Mile Island* (the Kemeny Report) (Kemeny, 1979).

The NRC carried out an investigation, reported in *Investigation into the March 28, 1979 Three Mile Island Accident by Office of Inspection and Enforcement* (the NRC Report) (NRC, 1979b). It also set up a task force, the findings of which are given in *TMI-2 Lessons Learned Task Force Final Report* (the Task Force Report) (NRC, 1979d).

Another report is *Analysis of Three Mile Island – Unit 2 accident by the Nuclear Safety Analysis Center* (NSAC) of EPRI (1979a).

Hearings were also held by the US Congress (US Congress, 1979) at which evidence was taken from managers, engineers, process operators and others.

The Accident at Three Mile Island gives the initial response of the HSE (1979a).

The TMI accident was a watershed in the development of nuclear power in the US and worldwide. After 1979, the ordering of new nuclear power stations in the US virtually dried up. Elsewhere, TMI has at the least heightened awareness of nuclear hazards.

In addition to the official reports mentioned, accounts of the TMI accident have been given in *Three Mile Island* by Stephens (1980) and by J.F. Mason (1979), Rubinstein (1979a, b), Collier and Davies (1980), Dunster (1980), H.W. Lewis (1980), Rogovin (1980), Schneider (1980) and Kletz (1982l, 1988h). A detailed timetable of the events during the accident is given by the NRC (1979b) and by J.F. Mason (1979).

Selected references on TMI are given in Table A21.1.

A21.1 The Company and the Management

The company which operated TMI was Metropolitan Edison (Met Ed).

Some of the TMI staff who involved in dealing with the incidents were

Station manager	Mr G. Miller
Station superintendent	Mr J. Logan
Superintendent of technical support	Mr G. Kunder
Shift supervisor	Mr W. Zewe
Shift foreman	Mr F. Scheimann
Control room operators	Mr E. Frederick; Mr C. Foust
Others involved included Met Ed vice-president for generation	Mr J. Herbein
Babcock and Wilcox site representative	Mr L. Rogers

A21.2 The Site and the Works

TMI is situated on the Susquehanna River, some 10 miles south-east of Harrisburg, Pennsylvania.

A21.3 The Process and the Plant

The plant consisted of two PWRs of approximately 900 MWe each. Unit 1 had been in commercial service since 1974 and Unit 2 since December 1978.

The contractors for the reactor plant were Babcock and Wilcox.

The nuclear reactor system is shown in Figure A21.1. The reactor itself is a pressure vessel containing the reactor core. The fuel in the core is enriched uranium dioxide pellets encased in zirconium alloy tubing. There are some 37,000 of these fuel pins arranged in clusters in the core. The core is cooled by the primary cooling system containing water at a high pressure ($\ll$15.2 MPa) to prevent its boiling. The water acts not only as a coolant but also as a moderator.

Heat is removed from the reactor in this primary cooling circuit, the reactor cooling system (RCS), and used in the steam generators to generate steam to drive a pair of turbogenerators. The primary cooling system consists of two independent loops containing water at high pressure.

Since the volume of the cooling water changes with temperature, it is necessary to have some free space or 'bubble' in the primary circuit to control the system pressure. This is provided by the pressurizer, which is equipped with electrical heating to raise steam and thus increase the pressure, and cold water sprays to condense steam and thus lower the pressure. Steam can be blown off through a pilot-operated relief valve (PORV). The tail pipe from the PORV is run to the reactor coolant drain tank.

An emergency core cooling system (ECCS) is provided to give backup cooling. This consists of three separate systems. One is the high pressure injection (HPI) system which pumps borated water into the system at a pressure greater than the normal coolant pressure. Another is the core flooding system which automatically injects cold borated water into the system when the coolant pressure falls below about 4.1 MPa. The third is the low pressure injection system which operates at 2.8 MPa. This takes water either from a large tank of borated water or from the dump of the containment building and is thus capable of keeping up recirculation indefinitely.

The reactor, the primary cooling circuit and the steam generators are housed in a containment building which is

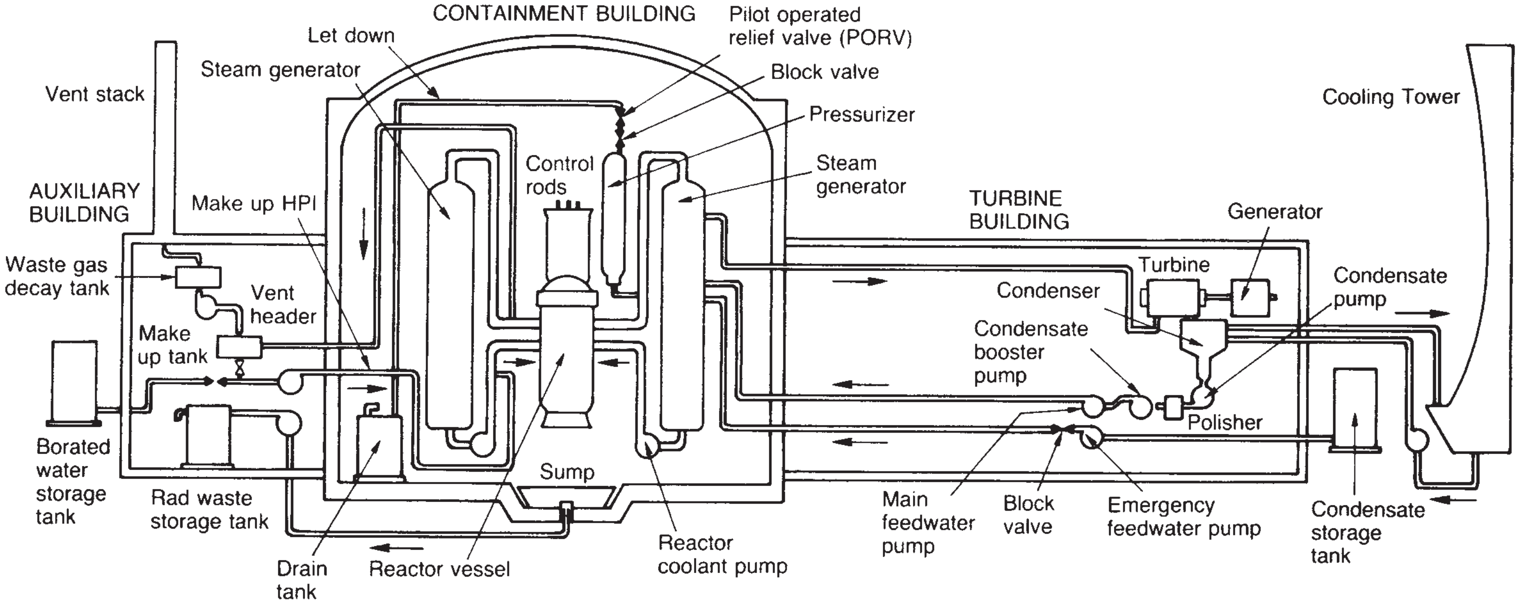

Figure A21.1 *Simplified flow diagram of TMI 2 nuclear power plant (Kemeny, 1979)* leak-tight. The containment is designed to retain the contents of the primary circuit in the event of a major leak.

The containment building has a spray system containing dilute sodium hydroxide. The spray is triggered by high containment pressure and is intended in the event of a loss of coolant accident to cool down the contents of the containment and to scrub out iodine.

The turbogenerator set is housed in a separate building which also contains the condensate and water treatment plants. Feedwater for the secondary circuit is from the condenser. The condensate water is purified by ion exchange in a condensate polishing system, a package unit.

The water converted to steam on the secondary side in the steam generators is supplied to them by the main feedwater pumps. These are backed up by auxiliary, or emergency, feedwater pumps. Both sets of feedwater pumps are housed in the turbine building.

The control room is a typical one and is shown in Figure A21.2.

A21.4 Events Prior to the Excursion

Some 2 days prior to the incident, routine testing had been done on the valves on the auxiliary feedwater pumps. Two of the valves, the 'twelve valves', had inadvertently been left shut.

For some 11 hours before the incident, the operators had been trying to clear a blockage in the condensate polishing system. In order to do this use was made of compressed air. The service air line used for this purpose was cross-connected to the instrument air line. The pressure of the air in the instrument line was less than that of the water in the units and some water got into the instrument air line, despite the presence of a non-return valve on that line. This water found its way to some of the plant instruments.

Another feature was a persistent slight leak from either the regular safety valves or the PORV.

A21.5 The Excursion – 1

An account is now given of the events which constituted the excursion. A timetable of the events is given in Table A21.2 Sections A and B showing the events and phases, respectively. The trend records of the RCS parameters are shown in Figure A21.3.

At the time of the incident on 28 March, the reactor was operating under automatic control at 97% of its rated output of 961 MWe. The incident began when water which had entered the instrument air line caused the isolation valves on the condensate polishing system to drift shut and the condensate booster pump to lose suction pressure and trip out. The main feedwater pumps in the secondary circuit then tripped and almost immediately the main turbine tripped. The time was 4.00.37.

Valves allowing steam to be dumped to the condenser opened, and the auxiliary feedwater pumps started up. At the steam generators, the removal of heat from the RCS fell, and the pressure of the RCS rose. Within 3–6 s the PORV set pressure of 15.5 MPa was reached and the valve opened, but this was insufficient to relieve the pressure, and at 8 s in, pressure rose to 16.6 MPa, the set point for reactor trip. The control rods were driven into the core to stop the reaction.

The RCS pressure now fell below the PORV set pressure, but the valve failed to shut. However, the valve position indicator in the control room, which actually indicated not the position of the valve but the signal sent to it, showed the valve as closed. The RCS continued to lose water through the open PORV.

In the secondary circuit condensate was no longer being returned to the steam generators, because the valves on the condensate polishing system had closed. The auxiliary feedwater pumps were running, but the valves between the pumps and the steam generators were also, inadvertently, closed. At 1 min 45 s into the incident the steam generators boiled dry.

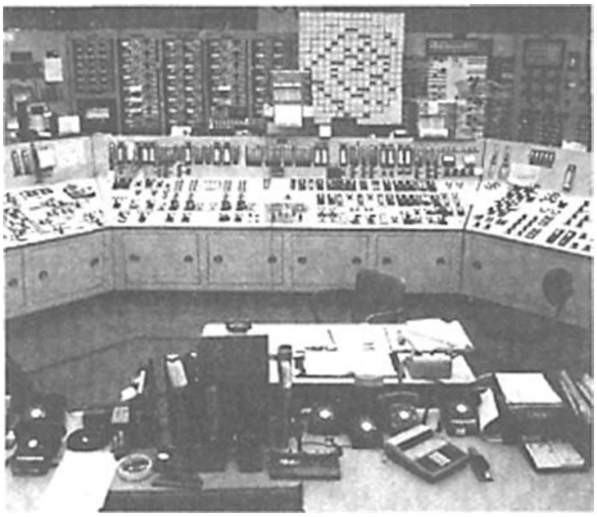

Figure A21.2 *Control room TMI 2 (Kemeny, 1979)*

Table A21.2 *Timetable of events at Three Mile Island*

A Timetable (first hours) (after Dunster, 1980)

Absolute time[a]	Time into incident	
4.01	zero	Feed water pump fails
		Pressure rise occurs in primary circuit
		Relief valves open
	8 s	Reactor shut-down
	13 s	PORV fails to close but indicates closure in the control room
		Extra cooling water (normal) injected by the operator
4.02	1 min 45 s	Steam generators dry out
4.03	2 min	Pressure in primary circuit falls and emergency cooling water injection started
4.04	3 min 30 s	Indication of high level of water in the pressurizer causes operator to shut off one emergency cooling pump
4.06	5 min 30 s	Stem generated in the core
		Operators drain off small volumes of primary water in response to rising level in pressurizer
4.11	11 min	Alarm indication of a high level of water in the containment building sump
		Sump water being pumped to auxiliary building
4.39	39 min	Sump pumps stopped by operator
5.00	60 min	Primary coolant pumps vibrating due to pressure of steam
5.14	1 h 14 min	Two primary pumps stopped by operator
5.45	1 h 45 min	Two remaining primary pumps stopped by oprator
5.50	1 h 50 min	Temperature in outlet ducts high enough to show presence of superheated steam – sigificance not recognized
6.22	2 h 22 min	Block valves on the relief valve lines closed by operators
7.00	3 h	Site emergency declared
7.20	3 h 20 min	Indication of 800 rem/h in containment building
7.24	3 h 24 min	General emergency declared
8.00	4 h	Containment building isolated automatically but operators continue to transfer primary let-down water to tanks in the auxiliary building
8.25	4 h 25 min	Local radio carried item concerning general emergency

B Phases (Collier and Davies, 1980)

Phase	1	Turbine trip 0–6 min
	2	Loss of coolant
	3	Continued depressurization 20 min–2 h
	4	Heat-up transient 2–6 h
	5	Extended depressurization 6–11 h
	6	Repressurization and ultimate establishment of stable cooling mode 13–16 h
	7	Removal of hydrogen bubble 1–8 d

[a] Absoulte times are approximate; the turbine trip was at 4.00.37.

Meanwhile the RCS pressure was dropping. At 2 min the pressure fell to 11 MPa at which point the first of the ECCS systems, the HPI system, came on and injected high pressure water. The liquid level in the pressurizer, however, was rising.

The display of liquid level was an indicator of the level of fluid in the pressurizer, but no longer of the mass of water; the liquid now contained steam bubbles and had thus been rendered less dense. To this extent the level display had become misleading.

The operators became concerned that the HPI system was increasing the inventory of water in the RCS, that the steam bubble in the pressurizer would be lost and that the circuit would become full of water and thus go 'solid'. At 4 min 38 s they therefore shut down one of the HPI pumps and throttled back the other.

With water passing through the PORV the pressure in the reactor coolant drain tank built up and at 7 min 45 s the reactor building sump pump came on, transferring water to the waste tanks in the auxiliary building.

At 8 min the operators realized that the steam generators were dry. They found that the auxiliary feedwater system valves were closed and opened them, thus restoring feedwater to the steam generators.

At 60 min the operators found that the RCS pumps were vibrating. This was due to the presence of steam, though they did not realize this. At 1 h 14 min they shut off the two pumps in Loop B to prevent damage to the pumps and pipework, with possible loss of coolant, and at 1 h 40 min shut off the two pumps in Loop A.

At 2 h 18 min the PORV block valve was at last shut off, thus stopping the loss of water from the RCS. The RCS pressure then began to rise.

In the two hours since the turbine trip periodic alarms had warned of low level radiation in the containment building. At about 2 h in, there was a marked increase in the

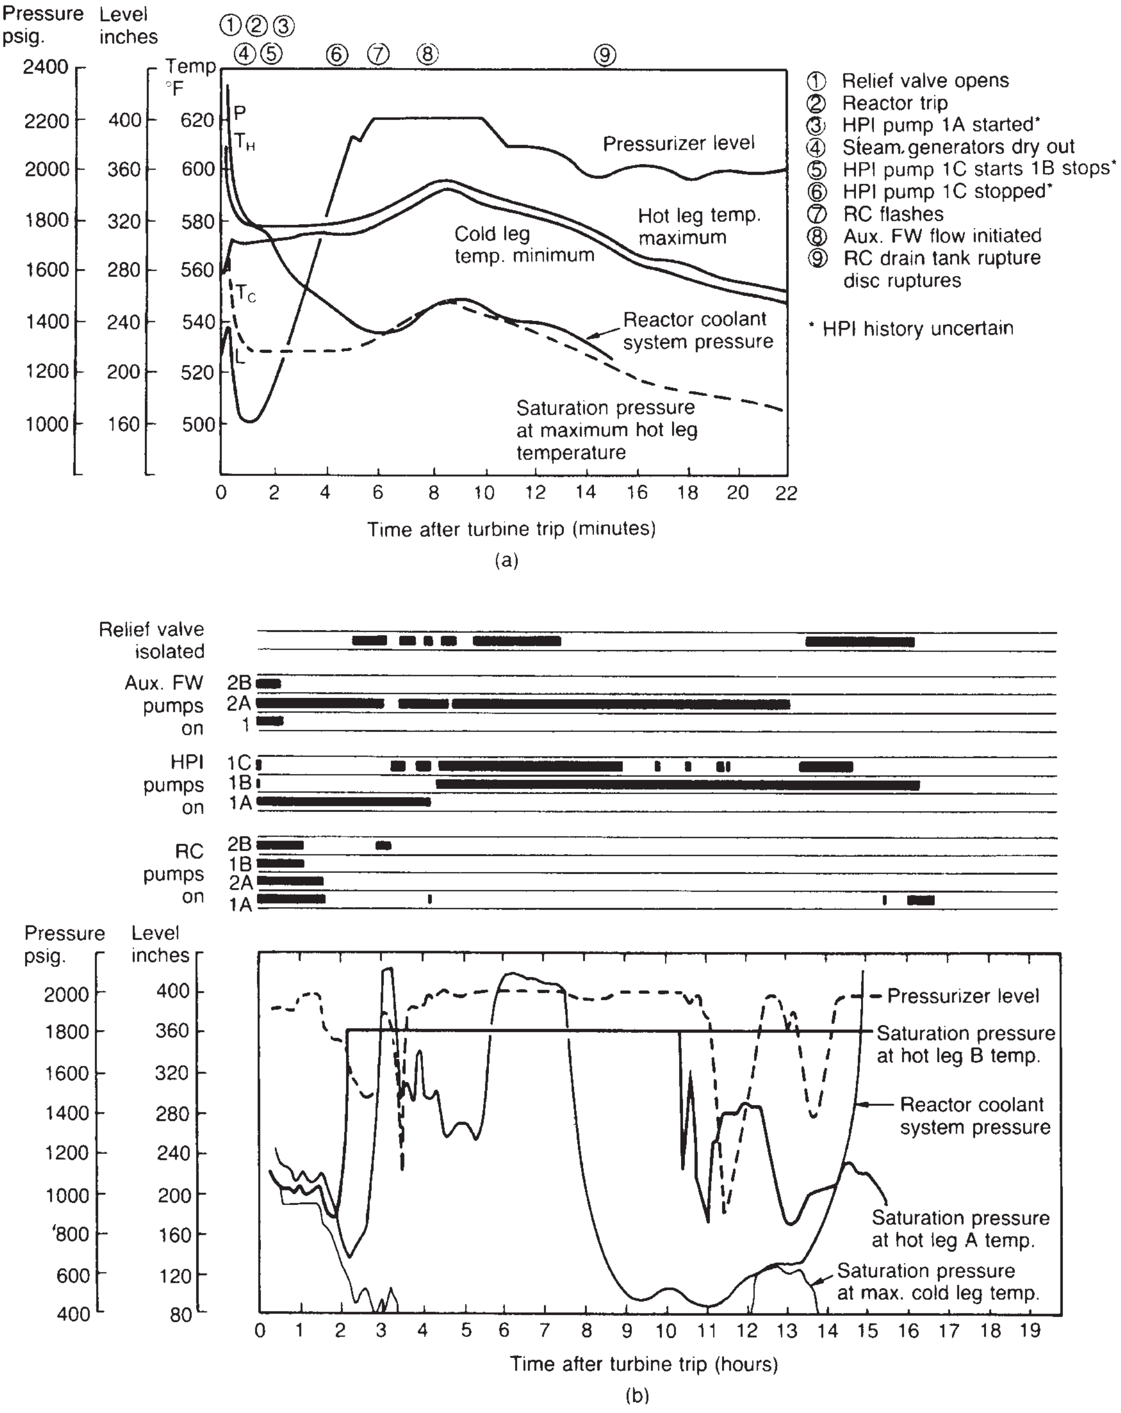

Figure A21.3 *Trend records of reactor cooling system parameters at TMI 2 (Collier and Davies, 1980): (a) parameters in minutes following turbine trip; and (b) parameters in hours following turbine trip* radiation readings. By 2 h 48 min in, high radiation levels existed in several areas of the plant. At 2 h 55 min a site emergency was declared.

Attempts were made to restart the RCS pumps. One pump in Loop B operated for some 19 min but was shut down again by vibration trips at 3 h 13 min.

Meanwhile, high radiation levels had been measured in the containment building. At 3 h 30 min a general emergency was declared.

At some point, perhaps about 4 h in, the station manager appears to have realized that the reactor core had suffered damage.

From 4 h 30 min attempts were made to collapse the steam bubbles in the RCS loops, but without success and at 7 h these efforts were abandoned.

The operators then tried to bring in the lower pressure cooling system by reducing pressure in the RCS. They began at 7 h 38 min by opening the PORV block valve. At 8 h 41 min the pressure fell to 4.1 MPa at which point the core flooding system operated.

One consequence of the exposure of the core was that a steam-zirconium reaction occurred, generating hydrogen. During the depressurization, hydrogen from the RCS was vented into the containment building. At 9 h 50 min, there occurred in the containment building what was apparently a hydrogen explosion. There was a thud and a pressure spike of 0.19 MPa occurred. The sprays came on for some 6 min. However, the nature of the event was not immediately understood.

By this time the reactor had been stabilized, although it had suffered core damage.

When the significance of the event in the containment building became appreciated, concern grew about a possible explosion of a hydrogen bubble there.

A21.6 The Emergency and the Aftermath

As already described, a site emergency was declared at 7.00 on 28 March. At 7.24 a general emergency was declared. The emergency which then unfolded over the next week or so is described in the Kemeny Report.

The plant was contacted by the local WKBO radio station. The radio station asked what kind of emergency it was. They were told by the company manager of communications services that it was a general emergency, a ‘red-tape’ sort of thing required by the NRC when certain conditions exist, but that there was no danger to the public.

The emergency did not end with the establishment of stable operation. The following day, the core damage was found to be more serious than first thought. The hydrogen bubble problem persisted over the next 8 days and caused particular concern. There were also a number of other problems, mainly associated with the large quantities of water contaminated with low level radioactivity. The levels of radioactivity in the atmosphere around the plant were monitored continuously.

The handling of the emergency in respect of evacuation developed into a protracted saga, of which only highlights need be mentioned. In addition to the company and the NRC, the state governor and the President became involved. On 29 March, meetings were held to decide whether to recommend evacuation. On 30 March, a radiation reading outside the plant, later found to be erroneous, led NRC officials to recommend evacuation. The local director of emergency preparedness was notified to stand by for an evacuation; he notified fire departments and had a warning broadcast that an evacuation might be called. Then the NRC chairman assured the Governor that an evacuation was not necessary. Later the Governor decided that pregnant women and pre-school children should be evacuated. Meanwhile, people around the plant had started to make their own arrangements, and many left. By 1 April, the NRC had concluded that the hydrogen bubble posed no threat but failed to announce this properly.

Operations to restore the situation at TMI-2 have lasted over a period of years (Masters, 1984).

A21.7 The Excursion – 2

The operators in the TMI-2 control room made a number of errors. Some of these were failures to make a correct diagnosis of the situation, others were undesirable acts of intervention.

The first was the failure to realize that the PORV had stuck open. The operators had an indication that the PORV had shut again, in the form of a status light. However, this light showed only the shut signal sent to the valve, not the valve position itself. They were also misled by the reading of high water level in the pressurizer.

There were several centra-indications, however, which pointed to the fact that the PORV was open. One was that the PORV outlet pipe was at a higher temperature than usual, 140°C instead of 90°C. Another was that the temperature and pressure in the pressurizer were lower than usual. The third was that there was a high level in the containment building sump. Later, the vibration of the primary coolant pumps was another indication.

Closely connected with this first diagnostic failure was the failure to recognize that the mass of primary coolant water had fallen. Here the operators were misled by the level measurement.

Turning to the interventions, at 2 min into the incident, the HPI pumps tripped in automatically, because the mass of water in the primary circuit was falling. Thirty seconds later, the operators, fearing that the system would fill right up with water and go ‘solid’, shut the HPI pumps off. This was the wrong action, because the primary circuit then continued to lose water.

Another counterproductive action was the shutting down of the primary coolant pumps. About 60 min into the incident, the pumps began vibrating. This was another clue that the primary circuit fluid was now a two-phase mixture of steam and water. The operators had been trained not to allow violent vibration of the pumps, which could damage them or the piping, and they shut the pumps down. The forced flow of cooling water through the reactor core ceased.

These failures of diagnosis and the fear of the system going solid have frequently been characterized as illustrations of mindset.

The operators were poorly served by the displays and alarms in the control room. Mention has already been made of the fact that some of the indicators did not actually display the variable of direct interest. There were a large number of alarms which were difficult to interpret.

A21.8 The Investigations

Principal investigations into the accident are the NRC Report, the Kemeny Report and the US Congressional hearings. These are described in this section. Recommendations given in the Kemeny Report and the Task Force Report are outlined in Section A21.9.

A21.8.1 NRC report

The NRC Report gives a detailed account of the TMI accident with a full chronology for the first 16 h containing 676 entries. There was little dispute about the basic facts. The investigations are significant mainly for their probing of the deeper causes.

A21.8.2 Congressional hearings

Hearings on the incident which are replete with information were held by the US Congress; they repay study.

Of particular interest here are the sessions dealing with the display and alarm systems. Extracts from the record on these two topics are given, respectively, in Tables A21.3 and A21.4 and are self-explanatory.

Table A21.3 *The display problem at Three Mile Island: evidence given to Congressional committee (after Lees, 1980f, based on US Congress, 1979)*

Weaver: I just want to say that is an extremely important point because one of the things we wanted to find out was how well they were in control. So you are raising the issue, I think, that because these gauges were off at one side they did not see them. Is that a possibility?
Eisenhut: It is certainly a possibility. In fact, that is why I said that is an area – the reason I highlighted it, it is a question area as to what happened to the pilot-operated relief valve, what kind of indications they had that the valve was still open.
Weaver: But they could have seen them?

. . .

Eisenhut: There were at least a couple of other instruments they could have used if those instruments were working. I do not know whether they were.
Weaver: The indications are that they did not see them for several hours; is that correct?
Eisenhut: At least a couple of hours. [p. 27]
Carr: We were told the other day that there was no direct level indicator in the reactor at the level of the coolant, that that had to be inferred from looking at other data, say the pressurizer pressure. Now we are saying that there is no direct indication of this valve at the top of the pressurizer, that we only got an indication, a direct indication on its mechanism rather than on its functioning, and that there were some backup inferences you could draw from other instruments which would lead someone to assemble some data. I suppose jumping way, way ahead of ourselves here I am wondering, is this a special feature of Babcock & Wilcox plants that on their gaging and instrumentation they do not use direct data, and then use the other stuff for backup? Or is this something throughout the nuclear industry, where there is a lot of data points and it leaves it to the operator to sort of assemble all of this, what is happening inside that building, in his head.
Stella: Valve positions normally are indicated by a mechanism which looks at the travel of the stem, which is to some degree on indirect reference to what the valve is actually doing, but a more direct method than you would get from looking at the solenoid which starts the event. [p. 30]

. . .

Stella: But as I tried to understand the accident, I reduced the number of program meters that I really wanted to know about to very few to try to make the judgement of what was going on. I think the operators can do that . . .

You can reduce the number that you really need to focus on to try to understand the event that you have had to relatively few. For example if you had a major LOCA, he would know very quickly what program meters that he ought to focus his attention on. He would have very quickly a response in the reactor building that says I have a discharge of a lot of high-energy fluid. I either have a break in my secondary system in the reactor building or the primary system. I immediately look at my primary system meters. Then I can tell if that was a primary system rupture. If it is a primary system rupture, I then know what program meters to track. So there is a hierarchy of logic built into the very many alarms that you see that point him at the right direction . . . . But this whole family of alarms and gages that you see, there is a hierarchy of logic built into it that, as you are trained to be an operator, you know what critical program meters to look for very quickly and eliminate or focus your attention in the right direction.
Carr: In the location of the alarms and gages and buzzes and switches and all that stuff, does the location on the panel follow that logic?
Stella: Yes. [p. 31]

. . .

Vento: One other thing before we go on to the other problem in the secondary system, which you did next. This relief valve, of course, is a key part of this, apparently. But there were some tailpipe temperature and some other indicators there that were also available. Who was responsible for watching those at this particular point? The tailpipe temperature?
Frederick: What you are talking about is the outlet temperature of the relief valve.
Vento: There is also a tank that this goes to that is not shown on here, and that has an indicator on it and a temperature and so forth. There is a thermocouple on here, and who was responsible for watching those in this particular process? It was just a generally shared thing?
Frederick: The points that you are talking about are not displayed. They are not on the console. They are in the computer. You have to manually call them up.
Vento: You have to call those things up. But were they not called up during this procedure at all?
Frederick: No.
Weaver: How many minutes are we in now? Where are we?
Faust: It is not a normal thing.
Frederick: About an hour.
Faust: We did not know a problem like that existed at the time.
Frederick: If the valve indicated shut, there is no reason to look at the downstream temperature. [p. 135]

. . .

Reis: It is a broad question, but as well as you can answer it, do you think that the control room provided you, in a timely fashion, in an easy-to-read fashion, the information you wanted and needed? And alternatively, in the course of the accident, were the communications in the control room such so that when someone at the panel needed conceptual information, in other words, this instrument, that instrument, and this gage are reading things that do not jibe together, that you had that sort of immediate access to an engineer? When did you get it? Did it work well, so that you were able to figure out what was really going on?
Frederick: The answer to the first question, the instruments, in my opinion, were not adequate. I can come up with a million questions on how to change them and the availability of additional input from the engineering staff.

It was not available to me, because I did not seek it out. I would give whatever question I had to the supervisor, and he would refer them to whoever he could as far as more operators, more engineers, to get more information. And he would bring back whatever suggestions there were if there were any. If things were that confusing, that I had to turn and ask somebody a question, I would wait for their response and their instructions on what to do next and then take the prescribed action according to what they suggested rather than what was on the panel.
Faust: I would way – well, I cannot change it much from what he said – we would continue to feed changes that we were seeing in the plant, to the supervisor; as well as if we thought we knew something that should be done, we would be saying that, too.
Reis: In terms of the layout of the plant, in general, do you think there could be some significant changes that would make your job a lot easier?
Frederick: Yes.
Faust: Definitely, [p. 155]

. . .

Cheney: It seems to me that is a key point. Has this ever been questioned before, whether or not the pressurizer level was an accurate reflection of the reactor coolant level, in a general sense, in terms of the basic design of the reactor?
McMillan: I think a lot of people have asked that question: What does the pressurizer level indicate to you?
Cheney: I would just like to come back to that basic question: Whether or not those operators at Three Mile Island on that day were trained to read that pressurizer level as anything other than indicating reactor level, coolant level in the reactor?
McMillan: Let us trace that through and see if we can find what evidence.
Cheney: Do you think that is some flaw in the design of the reactor?
McMillan: No, sir.
Cheney: Why not have a coolant level indicator from within the reactor itself?
McMillan: That has been suggested by a number of people, post Three Mile Island.
Weaver: Mr McMillan, how do you measure the level of water in the reactor vessel?
McMillan: You do not measure the level of water in the reactor vessel. . . .
Weaver: But is that not an important thing to know? Why do you not have something that tells us the level of the water?
McMillan: Well, I think -
Cheney: I guess I would like to follow up on this. [p. 232]

. . .

Weaver: Are you opposed, Mr McMillan, to water level measurement in the reactor vessel?
McMillan: It is a difficult problem, yes. But I am not at this point saying it is insurmountable . . .
Weaver: I would say the first thing I was going to do, if I were going to design a nuclear plant, is to make sure we knew what the water level was. [p. 237]

---

[a] In addition to the personnel identified in Section A21.1, the transcript extracts given above refer to the following: Mr Cheney, Mr Vento, Mr Weaver, all Congressmen; Mr Reis, Congressional staff; Mr D.Eisenhut, Deputy Director, Division of Operating Reactors, Office of Nuclear Reactor Regulation, NRC; Mr MacMillan, Vice-President, Nuclear Power Generation Division, Babcock and Wilcox Co.

Table A21.4 *The alarm problem at Three Mile Island: evidence given to Congressional committee (after Lees, 1980e, based on US Congress, 1979)*

Weaver: The plant manager told me he thought 100 audio alarms were going off at one time.
Stella: Is that what he told you?
Weaver: Yes
Stella: I would not be surprised.
. . .
Weaver: All occurring in the control room?
Mattson: Yes.
Carr: And there is no instrumentation that helps the operator sort out the order of importance of these alarms, or the order of importance of gages or lights or switches; right?
Mattson: Only the training.
Carr: Only the training to assemble all of these instruments and react in split seconds, [p. 31]
. . .
Weaver: How are people able to differentiate between these various alarms?
Michelsen: I am not a human factors engineer. I have never studied control rooms enough to understand that area at all. It is a very good question. I have asked it sometimes myself. [p. 47]
. . .
Higgins: There were a lot of short-term problems that were being addressed also; that is, equipment problems, loss of power, additional alarms that continued throughout the day, and we did not mention the number of alarms; there were a large number of equipment starts and stops, large number of individual problems . . . [p. 97]
. . .
Weaver: Would you describe the alarms that were going off? Were they going just constantly or was it -
Higgins: One would occur; the operators would address that. And then another one, perhaps a little bit later another one, or if you have a particular event, a specific event, for example the hydrogen burning in the containment might generate several; or a particular release of radioactivity from an area in the auxiliary building might generate several related alarms. Like generally there are a lot of indicators of a particular event as Mr Michelson described, on relief valve. You have got a relief valve tailpipe temperature alarm; you have got an alarm in the reactor drainpipe, I believe; level indications, and perhaps alarms associated with those system pressure alarms.
All this has to do with one relief valve lifting, so when a particular event occurs, you may get several related alarms, all of which have to be addressed. [p. 99]
. . .
Higgins: If you have a scram, many alarms do come in as a result of that. Some are normal; some indicate things not being normal. And it is up to the operator by his training to distinguish which ones he expects, which ones not to expect, that type of thing. [p. 100]
. . .
Higgins: There was a tremendous amount of activity going on in the control room. A lot of people were involved with a lot of the different problems, and that was one of many things. Operators were – alarms were going off; pumps were being started and stopped; valves were being cycled, and this* was just one of a myriad of those things that was occurring throughout the entire day. And I was thoroughly not able to follow what was going on. And I did not pick it up at all. [p. 111]
[*A spike on a recorder probably indicating a hydrogen burn – FPL].
. . .
Frederick: The alarms – this is a big problem. There is only one audible alarm in the control room for the 1600 alarm

windows that we have, in other words, the ones that are displayed on the front of the console along with the ones on the reverse panel. So that during the emergency, I made a point of announcing that I did not want anybody to acknowledge the alarm, that is, push the acknowledgement to silence the alarm, because that would make all the windows stop flashing, and I wanted to read them all to see what was happening. As we began to run out of ideas, I wanted to review all of the alarms that we received to see if anything was happening that we could not see.

. . .

Frederick: There are several steps in the alarm process. As the alarm comes in, it sounds an alarm and a flashing light. As long as the alarm stays in – and you push the button, and the light will go solid. If in the meantime the alarming condition clears itself or goes away and you push the button, the light will go out and you will not be able to tell that it ever came in. If you have three or four alarms at the same time, only one may stay lit out of the three or four. We had probably 100 or 200 alarms flashing within the first few minutes.

. . .

Frederick: I would not be able to establish the chronology. I just wanted to see what systems were affected by the transient and if we could see something. There are some alarms you expect to get. If you read over them, you just discount them as being normal. But there may be a few that come in that you had not expected, and those are the ones I was looking for. [p. 136]

. . .

Frederick: No. The sequence of alarms that comes out of the computer that they were able to read later on was backlogged. The alarms came in 100 at a time. The computer, the IBM typewriter just types them out one at a time. So as they were coming in rapidly, probably 10 or 15 per second, it just could not keep up. So there was a backlog of maybe 2 or 3 h.

Faust: I do not know what time this fits into, but we had problems with the alarm typewriter, too, at this time. I do not know what it was, but the easiest way for me to say it is, it sort of started eating the paper. In other words, it got off the track. [p. 137]

. . .

Vento: Obviously the proper procedure here would have said that 300° or 280° in the tailpipe should have been an indication.

Frederick: That is the point he is talking about. In other words, what came out of the computer on the typewriter was an alarm that said: Temperature hot. But we could not see that, because the alarm typewriter was backlogged several hours. [p. 139]

. . .

Weaver: Now I am troubled by the newspaper reports. One report, early on, had it that there was just page after page of computer printout of question marks.

Miller: Looking back – and we can come back to you with further information, but there was a period of time in the first 2 to 3 h where the computer failed, I believe.

Zewe: Yes, for over an hour period, it did not give us any information.

Cheney: You mean you would query it and nothing would happen?

Zewe: No. The question marks, periods, and so forth, the computer had hung up, where it really did not scan the parameters and print on in a fashion where we could interpret it.

Cheney: It was unusable.

Miller: I thing Bill would back this up. He was not using that totally. He was just using his console to operate the plant, so when that went out, he just had to go away from it.

Weaver: What caused this? What was going on? What happened? We have it here in the chronology that 1 hour 13 to 2:37 – in other words -

Miller: I think, in fairness, the machine has got a tape, disc, and that sort of thing. It has experienced problems. It is not a vital piece of equipment to Bill's use of the emergency procedures or operations of the plant, so I would guess Bill would just simply have told an electrical engineer to call someone in and go on with the console.

Weaver: You do not have to have it in any way?

Zewe: No, it is just an operator's tool, but it is not anything that is really that critical to the operation. [p. 175]

. . .

---

[a] In addition to the personnel identified in Section A21.1 and Table A21.3, the transcript extracts given above refer to the following: Mr Carr, Congressman; Mr Stello, Director, Division of Operating Reactors, Office of Nuclear Reactor Regulation, NRC; Mr Mattson, Division of System Safety, Office of Nuclear Reactor Regulation, NRC; Mr Michelson, Nuclear Engineer, Tennessee Valley Authority; and Mr Higgins, Region I, Office of Inspection and Enforcement, NRC.

A21.8.3 Kemeny Report

The Kemeny Report gives an account of the accident, from 29 March to 2 April, presents findings and makes recommendations. Some findings are described in this section.

The reports starts with what it calls 'people-related problems'. It states

> Popular discussions of nuclear power plants tend to concentrate on questions of equipment. Equipment can and should be improved to add further safety to nuclear power plants, and some of our recommendations deal with this subject. But as the evidence accumulated, it became clear that the fundamental problems are people-related problems and not equipment problems.
>
> When we say that the basic problems are people-related, we do not mean to limit this term to shortcomings of individual human beings – although these do exist. We mean more generally that our investigation has revealed problems with the 'system' that manufactures, operates and regulates nuclear power plants. There are structural problems in various organizations, there are deficiencies in various processes, and there is a lack of communication among key individuals.
>
> We are convinced that if the only problems were equipment problems, this Presidential Commission would never have been created. The equipment was sufficiently good that except for human failures, the major accident at Three Mile Island would have been a minor incident. But, wherever we looked, we found problems with the human beings who operate the plant, with the management that runs the key organization, and with the agency that is charged with assuring the safety of nuclear power plants. (p. 8)

The form frequently taken by this problem is described as follows: 'In the testimony we received, one word occurred over and over again. That word is "mindset".' (p. 8)

The report is critical of the approach taken to control of the industry, stating:

> We note a preoccupation with regulations. It is, of course, the responsibility of the Nuclear Regulatory Commission to issue regulations to assure the safety of nuclear power plants. However, we are convinced that regulations alone cannot assure safety. Indeed, once regulations become as

> voluminous and complex as those regulations now in place, they can serve as a negative factor in nuclear safety. The regulations are so complex that immense efforts are required by the utility, by it suppliers and by the NRC to assure that regulations are complied with. The satisfaction of regulatory requirements is equated with safety. This Commission believes that it is an absorbing concern with safety that will bring about safety – not just the meeting of narrowly prescribed and complex regulations. (p. 9)

The report makes various criticisms of the NRC, of which a sample, changed in order, are:

> We found serious managerial problems within the organization. These problems start at the very top . . . It is not clear to us what the precise role of the five NRC commissioners is, and we have evidence that they themselves are not clear what their role should be . . . NRC's primary focus is on licensing and insufficient attention has been paid to the ongoing process of assuring safety . . . NRC is vulnerable to the charge that it is heavily equipment-oriented, rather than people oriented . . . We are extremely critical of the role the organization played in the response to the accident . . . NRC has sometimes erred on the side of the industry's convenience rather than carrying out its primary mission of assuring safety . . . (pp. 19 – 21)

The Commission identifies an over-concentration on large accident hazards:

> We find a fundamental fault even with the existing body of regulations. While scientists and engineers have worried for decades about the safety of nuclear equipment, we find that the approach to nuclear safety has a major flaw. It was natural for the regulators and the industry to ask: 'What is the worst kind of equipment failure that can occur?' Some potentially serious scenarios, such as the break of a huge pipe that carries the water cooling to the nuclear reactor, were studied extensively and diligently, and were used as the basis for the design of plants. A preoccupation developed with such large-break accidents as did the attitude that if they could be controlled, we need not worry about the analysis of 'less important' accidents. (p. 9)
>
> A potentially insignificant incident grew into the TMI accident, with severe damage to the reactor. Since such combinations of minor equipment failures are likely to occur much more often than the huge accidents, they deserve extensive and thorough study. (p. 9)

The report is critical of organizational failure to follow through safety issues:

> We find that there is a lack of 'closure' in the system -that is, important safety issues are frequently raised and may be studied to some degree of depth, but are not carried through to resolution; and the lessons learned from these studies do not reach those individuals and agencies that most need to know about them. (p. 11)

The report reopens the issue of the influence of the operator in a developing reactor emergency. The conventional approach has been that any action taken by the operator is likely to be beneficial. It gives this view as an example of designers' mindset: 'They concentrated on equipment, assuming that the presence of operators could only improve the situation – they would not be part of the problem', (pp. 8 – 9).

On the handling of the emergency the Commission comments:

> We are disturbed both by the highly uneven quality of emergency plans and by the problems created by multiple jurisdictions in case of a radiation emergency. Most emergency plans rely on prompt action at local level to initiate a needed evacuation or to take other protective action. We found an almost total lack of detailed plans in the local communities around Three Mile Island. It is one of the many ironies of this event that the most relevant planning by local authorities took place during the accident. In an accident in which prompt defensive steps are necessary within a matter of hours insufficient advance planning could prove extremely dangerous. (p. 15)

The report contains a number of supplemental views by individual members of the commission, one of which is by Professor T.H. Pigford. He is critical of the NRC's approach to safety, which he characterizes as lacking in experienced personnel; failing to take a comprehensive approach with quantified safety objectives and rational priorities; and prone to introduce arbitrary requirements. He calls it 'A stifling approach. The existing process inhibits the interchange of technical information between the NRC and industry. It discourages innovative engineering solutions'. On human factors aspects he states

> The emphasis in this report upon equipment versus people obscures the fact that the equipment itself is only one product of the defense-in-depth or multiple-barrier design approach, which also encompasses the analysis of how components must perform and how systems of equipment must operate. The accident demonstrated that this system of equipment performed better than expected.
>
> The nature of the people-related problem needs clarification. One such problem – and a most serious one – was the errors made by the operators and the operator-supervisors, whose training was insufficient in scope and understanding. Another was failure of many individuals to respond adequately to earlier experience from other reactors and to other advance information that might have alerted the operators and avoided the accident.

A21.9 Some Lessons of Three Mile Island

A21.9.1 Kemeny Report recommendations

The Kemeny Report and the Task Force Report both give extensive recommendations. The heads of these recommendations are shown in Table A21.5, in Sections A and B, respectively.

The Kemeny Report recommends that the NRC should be restructured as a new independent agency in the executive branch and that the ACRS should be strengthened.

The report states: 'To the extent that the industrial institutions we have examined are representative of the nuclear industry, the nuclear industry must dramatically change its attitude towards safety and regulations'. It goes on The industry should establish a program that specifies appropriate safety standards including those for management, quality assurance, and operating procedures and practices, and that conducts independent evaluations'.

Improvements in operator training are called for, with particular emphasis on the use of simulators.

Table A21.5 Heads of some principal recommendations on Three Mile Island

A Presidents Commission (Kemeny, 1979)
Nuclear Regulatory Commission
Utility and it suppliers
Training of operating personnel
Technical assessment
Worker and public health and safety
Emergency planning and response
Public's right to information
B 'Lessons Learned' Task Force (Nuclear Regulatory Commission, 1979b)
Personnel qualifications and training
Staffing of control room
Working hours
Emergency procedures
Verification of correct performance of operating activities
Evaluation of operating experience
Man–machine interface
Reliability assessments of final designs
Review of safety classifications and qualifications
Design features of core-damage and core-melt accidents
Safety goal for reactor regulation
Staff review objectives
NRR Emergency Response Team

Under the heading of technical assessment, the report deals with equipment for information display in the control room and for mitigating the consequences of accidents and recommends a formal safety assurance programme involving hazard identification and assessment.

The report recommends that there should be a requirement for an emergency response plan.

It also makes recommendations on worker and public health in relation to nuclear hazards and on the public's right to information.

A21.9.2 Task Force Report recommendations

The recommendations of the Task Force Report are summarized in Section B of Table 21.5. They deal particularly with operator training and with the man-machine interface.

The report calls for a thorough review of control room design and for development of aids to assist the operator in assessing the status of the plant and in analysing disturbances and alarms. It proposes the development both of a plant safety status display system and of a disturbance analysis system (DAS).

On the former the report states

> Each licensee should be required to define and adequately display in the control room a minimum set of plant parameters (in control terminology, a state vector) that defines the safety status of the nuclear power plant. The minimum set of plant parameters should be annotated for sensor limits, process limits, and sensor status. The annotated set of parameters should be presented to the operator in real time by a reliable, single-failure-proof system located in the control room. (p.A-12)

Table A21.6 Some lessons of Three Mile Island

Regulatory control of major hazard installations
People-related versus equipment-related problems
Formal safety assurance
Relative importance of large and small failures
Influence of operator in an emergency
Fault diagnosis by the process operator
Accident management for major hazard installations
Follow-up of safety issues
Learning from precursor events
Package and other ancillary units
Display of variable of interest
Plant status display and disturbance analysis systems
Abuse of instrument air
Limitations of non-return valves

A21.9.3 Some lessons

The Three Mile Island incident yields numerous lessons. Some of these are listed in Table A21.6. Many of these lessons are drawn in the reports just described.

Regulatory control of major hazard installations

The comments made in the Kemeny Report on the regulatory regime for US nuclear power plants under the NRC both echo those made in the Robens Report in the UK in 1972 and themselves find an echo in those of the Cullen Report on UK offshore installations in 1990. In all three cases the reports are critical of an approach which they find excessively prescriptive.

People-related versus equipment-related problems

The theme which runs through the Kemeny Report is that equipment-related problems have received attention at the expense of people-related problems. The account of these problems given in the report indicates clearly that the term refers not just to process operators, although operator problems were a central issue, but to management and management systems. Here too, the report may be said to look back to Robens and forward to Cullen.

Formal safety assurance

The Kemeny Report calls for a formal safety assurance programme for nuclear power plants involving hazard identification and assessment. In UK terms, its recommendations parallel those of the ACMH for onshore plant and of the Cullen Report for offshore installations, which uses the term 'formal safety assessment'.

Relative importance of large and small failures

Engineers in the nuclear industry had tended to concentrate their attention on major failures, notably the large loss of coolant accident, to the relative neglect of lesser events, such as a small, or at least slower, loss of coolant, such as actually occurred at TMI. Yet, as the incident showed, such lesser events can escalate. Moreover, lesser events occur much more frequently. There needs to be a more balanced approach which addresses small as well are large failures.

Influence of operator in an emergency

It has been a basic assumption in the industry that in a nuclear emergency operator action would be beneficial, and that the longer the time available for such action the higher the probability that it would be taken. TMI showed that this is not necessarily so, and that operator action can be detrimental.

Fault diagnosis by the process operator

The incident highlighted the problem of fault diagnosis by the process operator under stress. It showed the limitations of fixed operating rules in dealing with abnormal situations and the dangers of tunnel vision, or mindset. In other words, it showed the inadequacy of rule-based behaviour and the need for knowledge-based behaviour and for training based on development of the latter.

Accident management for major hazard installations

TMI shows that a major accident poses a number of difficult problems and that it needs to be managed. This implies that accident management must be recognized as a specific requirement and planned in advance.

The handling of an emergency in the control room is one aspect of the problem, but there are many others. They include the identification, mobilization, direction and coordination of the necessary resources; planning for an emergency, both on-site and off-site; and handling of the media.

Follow-up of safety issues

The Kemeny Report is critical of the follow-up of safety issues, referring to a lack of closure. Safety issues which are raised and agreed to be valid need to be followed through to resolution. Personnel who most need to know should be informed.

Learning from precursor events

There had been previous incidents in which a PORV had been stuck in the open position, but the management of the TMI plant had no systematic approach to learning from such incidents.

Package and other ancillary units

Turning to some more detailed aspects, the incident started with a fault in the condensate polishing system, a package unit. It illustrates the point that the ancillary equipment and services should receive their due share of attention, starting with specification and continuing right through to operation.

Display of variable of interest

If a process variable is critical, it is highly desirable that the quantity which is displayed should be the variable of direct interest. At TMI there were two cases where this was not done. One is the water level in the pressure vessel. The other is the status of the PORV. The display showed the signal to the valve rather than the actual valve position.

Plant status display and disturbance analysis systems

TMI was a dramatic illustration of the difficulties faced regularly by process operators in interpreting displays and alarms, and of way in which these can be compounded by information overload. It highlighted the scope for the development of improved display and alarm systems and for the exploitation of computers to this end. The principal aids proposed were plant safety status display systems and disturbance analysis systems.

Abuse of instrument air

The air used to clear the blockage on the condensate polishing system was instrument air. It is bad practice to connect instrument air to the process, which can cause it to become contaminated.

Limitations of non-return valves

The entry of water into the instrument air system illustrates the limitations of a non-return valve. Such a valve is intended to stop bulk flow of fluid; it will not necessarily prevent the passage of trace quantities.

Appendix

22

Chernobyl

Contents

On Monday 28 April 1986 a worker at the Forsmark nuclear power station in Sweden put his foot in a radiation detector for a routine check and registered a high reading. The station staff thought they had had a radioactive release from their plant and the alarm was raised. However, as reports came in of high radioactivity in Stockholm and Helsinki, the source of the release was identified as the Soviet Union. In fact, an accident had occurred on Unit 4 at Chernobyl in the Ukraine some 800 miles from Sweden on Saturday 26 April.

At 1.24 on that day an experiment to check the use of the turbine during rundown as an emergency power supply for the reactor went catastrophically wrong. There was a power surge in the reactor, the coolant tubes burst and a series of explosions rent the concrete containment. The graphite caught fire and burnt, sending out a plume of radioactive material. Emergency measures to put out the fire and stop the release were not effective until 6 May.

The Soviet Government set up an investigatory team headed by N.I. Ryzhkov, President of the USSR Council of Ministers, to investigate. A report *The Accident at the Chernobyl Nuclear Power Plant and its Consequences* by the USSR State Committee on the Utilisation of Atomic Energy (1986) (the *USSR State Committee Report*) was presented in August 1986 to a meeting of experts at the IAEA in Vienna by V. Legasov.

Other accounts of the accident include *Summary Report on the Post-Accident Review Meeting on the Chernobyl Accident* by the IAEA (1986), *The Chernobyl Accident and its Consequences* by Gittus *et al.* (1987, 1988) (the *UKAEA Report), Chernobyl and the Safety of Nuclear Reactors in OECD Countries* by the NEA (1987), *Report on the Accident at Chernobyl Nuclear Power Station* by the NRC (1987b), *The Chernobyl Accident and its Consequences for the United Kingdom* by Worley and Lewins (1988) (the First *Watt Committee Report*), Chernobyl. *A Policy Response Study* by Segerstahl (1991) and *Five Years after Chernobyl: 1986–1991* by the Watt Committee (1991) (the Second *Watt Committee Report*) and by Franklin (1986) and Kletz (1988h).

The story of Chernobyl is told in *The Worst Accident in the World* by Haynes *et al.* (1986), *Mayday at Chernobyl* by Hamman and Parrott (1987), *The Chernobyl Disaster* by Haynes and Bojcum (1988), *Chernobyl. The Real Story* by Mould (1988) and *Ablaze* by Read (1993) and by Franklin (1986) and Kletz (1988h).

Selected references on Chernobyl are given in Table 22.1.

A22.1 The Operating Organization and the Management

Little information has become available concerning the organization operating the Chernobyl plant or about its management.

A22.2 The Site and the Works

The Chernobyl nuclear power station is situated in a region which at the time was relatively sparsely populated. There were some 135,000 people within a 30 km radius. Of these 49,000 lived in Pripyat to the west of the plant's 3 km safety zone and 12,500 in Chernobyl 15 km to the south-east of the plant.

There were four nuclear reactors on the site. The first pair had been built in the period 1970–77 and the second pair were completed in 1983.

A22.3 The Process and the Plant

Unit 4 at Chernobyl was designed to supply steam to two turbines each with an output of 500 MWe. The reactor was therefore rated at 1000 MWe or 3200 MWt.

Unit 4 was an RBMK-1000 reactor, which is a standard design widely used in the Soviet Union. The RBMK-1000, shown in Figure A22.1, is a boiling water pressure tube, graphite moderated reactor. The reactor is cooled by boiling water, but the water does not double as the moderator, which is graphite.

The design of the reactor avoided the use of a large pressure vessel. Instead, use was made of much smaller individual pressurized fuel channels. The reactor had 1661 fuel channels. There was in each one a fuel assembly, divided into two subassemblies, each containing 18 fuel elements.

The reactor contained 192 te of uranium enriched to 2%. The subdivision of the uranium into a large number of separately cooled fuel channels greatly reduced the risk of total core meltdown.

The reactor was cooled by water passing through the pressure tubes. The water was heated to boiling point and partially vaporized. The steam–water mixture with a mass steam quality of 14% passed to two separators where steam was flashed off and sent to the turbines, while water was mixed with the steam condensate and fed through downcomers to pumps which pumped it back to the reactor. There were two separate loops each with four pumps, three operating and one standby. This system constituted the multiple forced circulation circuit (MFCC).

The moderator used was graphite. The reactor contained a stack of 2488 graphite blocks with a total mass of 1700 te.

An emergency core cooling system (ECCS) was provided to remove residual heat from the core in the event of loss of coolant from the MFCC.

The reactor was provided with a control and protection system (CPS). The control system incorporated a control computer. There was a control system which controlled the power output of the reactor by moving the control rods, in and out. Automatic protective systems included a trip to bring in the ECCS and reactor shut-down trips. Reactor shut-down was effected by the insertion of control rods, and conditions which would trigger shut-down included loss of steam to the turbines and loss of level in the separators.

The reactor was housed in a containment built to withstand a pressure of 0.45 MPa. There was a 'bubble'

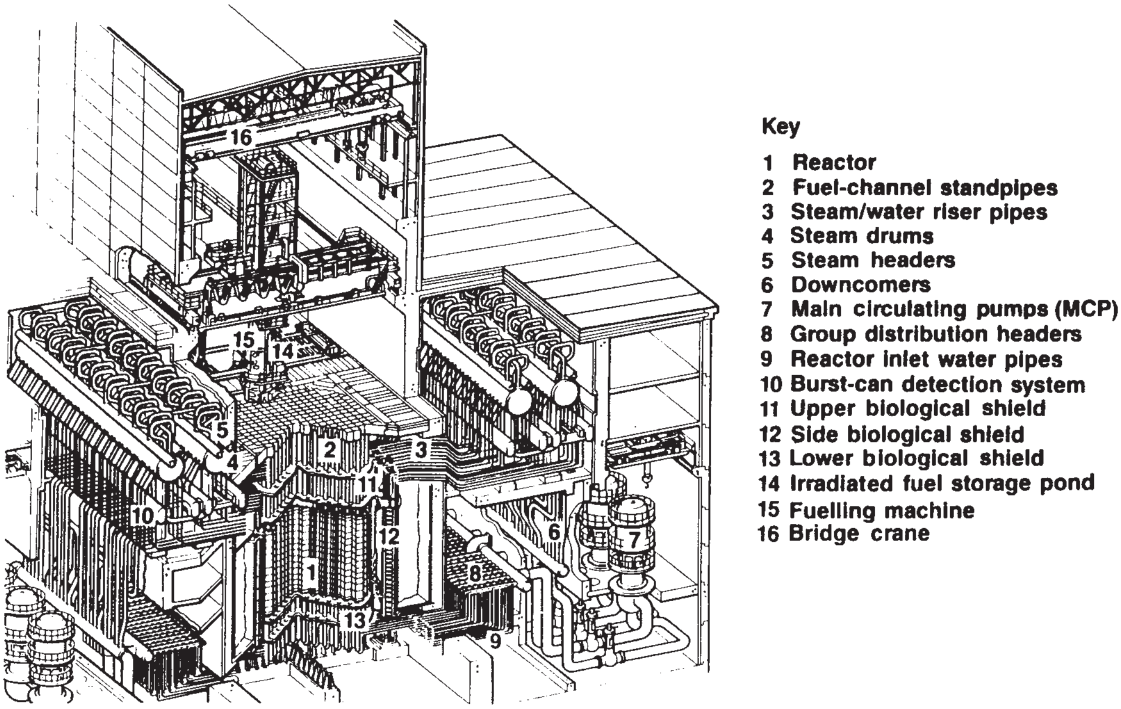

Figure A22.1 *Simplified flow diagram of Chernobyl Unit 4 (Nuclear Regulatory Commission, 1987b)*

condenser designed to condense steam entering the containment from relief valves or from rupture of the MFCC.

An important operating feature of the reactor was its reactivity margin, or excess reactivity. Below a certain power level the reaction would be insufficient to avoid xenon poisoning. It was therefore necessary to operate with a certain excess reactivity. This reactivity could be expressed in terms of the number of CPS control rods which would need to be inserted to counter it. The operating instructions stated that a certain excess reactivity was to be maintained; the equivalent number of control rods was 30.

Another important operating characteristic was the reactor's 'positive void coefficient'. An increase in heat from the fuel elements would cause increased vaporization of water in the fuel channels and this in turn would cause increased reaction and heat output. There was therefore an inherent instability, a positive feedback, which could be controlled only by manipulation of the control rods. Control of the reactor at normal power output presented little problem, but this feature made the reactor highly sensitive at low outputs.

A22.4 Events Prior to the Release

The origin of the accident was the decision to carry out a test on the reactor. Electrical power for the water pumps and other auxiliary equipment on the reactor was supplied by the grid with diesel generators as back-up. However, in an emergency there would be a delay of about a minute before power became available from these generators. The objective of the test was to determine whether during this period the turbine could be used as it ran down to provide emergency power to the reactor. A test had already been carried out without success, so modifications had been made to the system, and the fresh test was to check whether these had had the desired effect.

A programme for the test was drawn up. It included provision to switch off the ECCS during the test, apparently to prevent its being triggered during the test.

At 1.00 on 25 April the reduction of power began. At 13.05 Turbogenerator 7 was switched off the reactor. At 14.00 the ECCS was disconnected. However, a request was received to delay shutting down since the power output was needed. It was not until 23.10 that power reduction was resumed.

At some stage the trip causing reactor shut-down on loss of steam to Turbogenerator 8 was disarmed, apparently so that if the test did not work the first time, it could be repeated. This action was not in the experimental programme.

The test programme specified that rundown of the turbine and provision of unit power requirements was to be carried out at a power output of 700–1000 MWt, or 20% of rated output. The operator switched off the local automatic control, but was unable to eliminate the resultant imbalance in the measurement function of the overall automatic controls and had difficulty in controlling the power output, which fell to 30 MWt. Only at 1.00 on 26 April was the reactor stabilized at 200 MWt, or 6% of rated output.

Meanwhile the excess reactivity available had been reduced as a result of xenon poisoning.

It was nevertheless decided to continue with the test. At 1.03 the fourth, standby pump in one of the loops of the MFCC was switched on and at 1.07 the standby pump in the other loop.

A22.5 The Release – 1

With the reactor operating at low power, the hydraulic resistance of the core was less and this combined with the use of additional pumps resulted in a high flow of water through the core. This condition was forbidden by the operating instructions, because of the danger of cavitation and vibration. The steam pressure and water level in the separators fell and other process parameters changed. In order to avoid triggering the trips which would shut-down the reactor on these parameters, the trips were disarmed.

The reactivity continued to fall and at 1.22.30 the operator saw from a printout of the reactivity evaluation program that the available excess reactivity had fallen below a level requiring immediate reactor shut-down. Despite this the test was continued.

At 1.23.04 the emergency valves on Turbogenerator 8 were closed. The reactor continued to operate at about 200 MWt, but the power soon began to rise. At 1.23.40 the unit shift foreman gave the order to press the scram button. The rods went down into the core, but within a few seconds shocks were felt and the operator saw that the rods had not gone fully in. He cut off the current to the servo drives to allow the rods to fall in under their own weight.

Within 4 s, by 1.23.44, the reactor power had risen, according to Soviet estimates, to 100 times the nominal value.

At about 1.24, according to observers outside Unit 4, there were two explosions, the second within some 3 s of the first, and debris and sparks shot into the air above the reactor.

It is thought that the fuel fragmented, causing a rapid rise in steam pressure as the water quenched the fuel elements, so that there was extensive failure of the pressure tubes. The explosive release of steam lifted the reactor top shield, exposing the core. Conditions were created for reaction between the zirconium and steam, producing hydrogen. An explosion, involving hydrogen, occurred in and ruptured the containment building, and ejecting debris and sparks were seen.

Some 30 fires broke out.

The accident was aggravated by the fact that the 200 te loading crane fell onto the core and caused further bursts of the pressure tubes.

The stricken reactor is shown in Figure A22.2.

The timetable of these and the following events is shown in Table A22.2.

A22.6 The Emergency and the Immediate Aftermath

The fire brigades from Pripyat and Chernobyl set out at 1.30. The fires in the machine hall over Turbogenerator 7 were particularly serious, because they threatened Unit 3 also. These therefore received priority. By 5.00 the fires in the machine hall roof and in the reactor roof had been extinguished.

However, the heating up of the core and its exposure to the air caused the graphite to burn. The residual activity of the radioactive fuel provided another source of heat. The core therefore became very hot and the site of raging fire.

During the next few days the fire raged and a radioactive plume rose from the reactor. The accident had

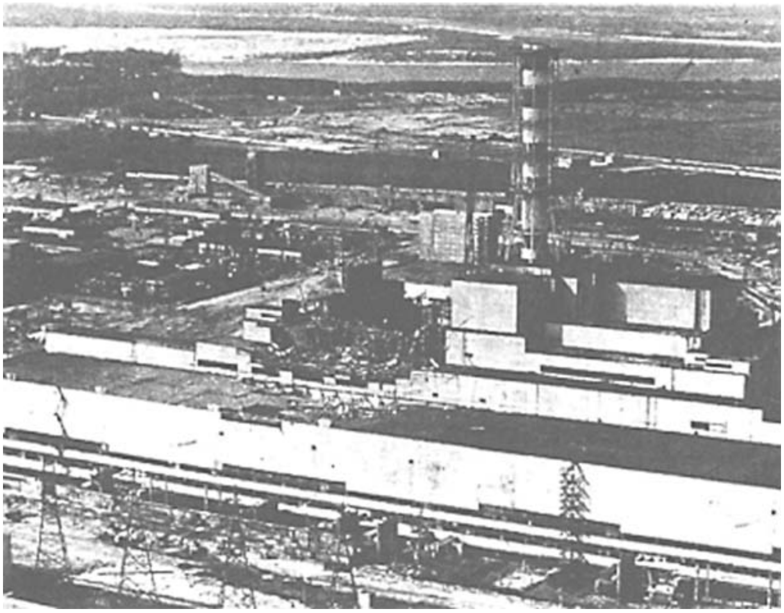

Figure A22.2 Reactor of Chernobyl Unit 4 after the explosions (ITAR-TASS)

Table A22.2 *Timetable of events at Chernobyl*

A	**Events prior to initial explosion**	
25 April	1.00	Reduction of power started
	13.05	Turbogenerator 7 disconnected
	14.00	ECCS disconnected
	23.10	Power reduction resumed
26 April	00.28	Operator switches off local automatic control, but is unable to eliminate resultant imbalance in measurement function of the overall automatic controls
		Power output falls to 30 MWt
	1.00	Reactor stabilized at 200 MWt (6% rated output)
	1.03	Standby pump switched on in one loop of MFCC
	1.07	Standby pump switched on in other loop of MFCC
	before 1.19	Trips on low steam pressure and low water level disabled
	1.22.30	Printout confirming fall in excess reactivity
	1.23.04	To begin test, stop valve on steam to Turbogenerator 8 closed
		Trip on closure of both turbogenerator steam stop valves disabled
	1.23.40	Scram button pressed to drop control rods
	1.23.40	Operator hears banging noises and sees rods stopping before they reach bottom; disengages servo drives to allow rods to fall under own weight
		Rapid increase in power
	1.23.48	First explosion – extensive failure of pressure tubes, explosive release of steam, top lifted off reactor
	1.24	Second explosion – explosion within reactor space, possibly involving hydrogen, pressure increase to several MP, rupture of containment building
		Numerous fires
B	**Events after initial explosion**	
26 April	2.54	Fire fighting units from Pripyat and Chernobyl arrive
	3.34	Most of fires in turbine room roof out
	3.54	Fire on reactor building roof out
	5.00	All fires, other than those in core, out
		Unit 3 shut-down
27 April	1.13	Units 1 and 2 shut-down
27 April		Start of smothering operation using helicopters
6 May		Discharge of radioactivity drops to several hundred Ci/h

become a major disaster. It was necessary to evacuate the population from a 30km radius round the plant and deal with the casualties and to take a whole range of measures to dampen and extinguish the fire, to cover and enclose the core, and to deal with the radioactivity in the surrounding area.

Three evacuation zones were established: a special zone, a 10km zone and 30km zone. The latter zone is shown in Figure A22.3. A total of 135,000 people were evacuated.

Accounts of the evacuation are incomplete and sometimes contradictory, but what appears to have happened is as follows. Within a few hours of the accident an emergency headquarters was set up in Pripyat. About 14.00 on 26 April there was an evacuation of some 1000 people from within a 1.6 km zone around the plant. A much larger evacuation took place about 14.00 next day, when about 1000 buses were brought in and within 2 h had evacuated some 40,000 people. However, it was not until some 9 days later that the authorities in Moscow ordered complete evacuation from a 30 km zone around the site.

First reports from Kiev spoke of no apparent concern, but as the nature of the disaster became known, parents hastened to send their children out of the city to relatives elsewhere.

A medical team was set up within 4 h of the accident and within 24 h triage of the 100 most serious cases had been effected.

A system was set up to control movements between the zones. People crossing the zone boundaries had to change clothing and vehicles were decontaminated.

In the immediate aftermath of the accident steps were taken to obtain the measurements essential to the control of the emergency. These included the measurement not only of the radioactivity in and around the plant, but also of conditions in the reactor relevant to bringing it under control. The latter was made more difficult by the fact that the regular measurement system had been disabled.

A decision had to be made whether to let the fire burn itself out or to smother it. In view of the hazard to the surrounding area, the latter course was chosen. A specialist team was assembled who began to cover the damaged reactor with compounds of boron, dolomite, sand, chalk and lead. Between 27 April and 10 May some 5000 te of material were dropped on the reactor by helicopter. By May 6 the release of radioactivity had decreased to a few hundred Ci/day and had ceased to be a major factor.

At the same time the core temperature was tackled by pumping nitrogen under pressure from the compressor

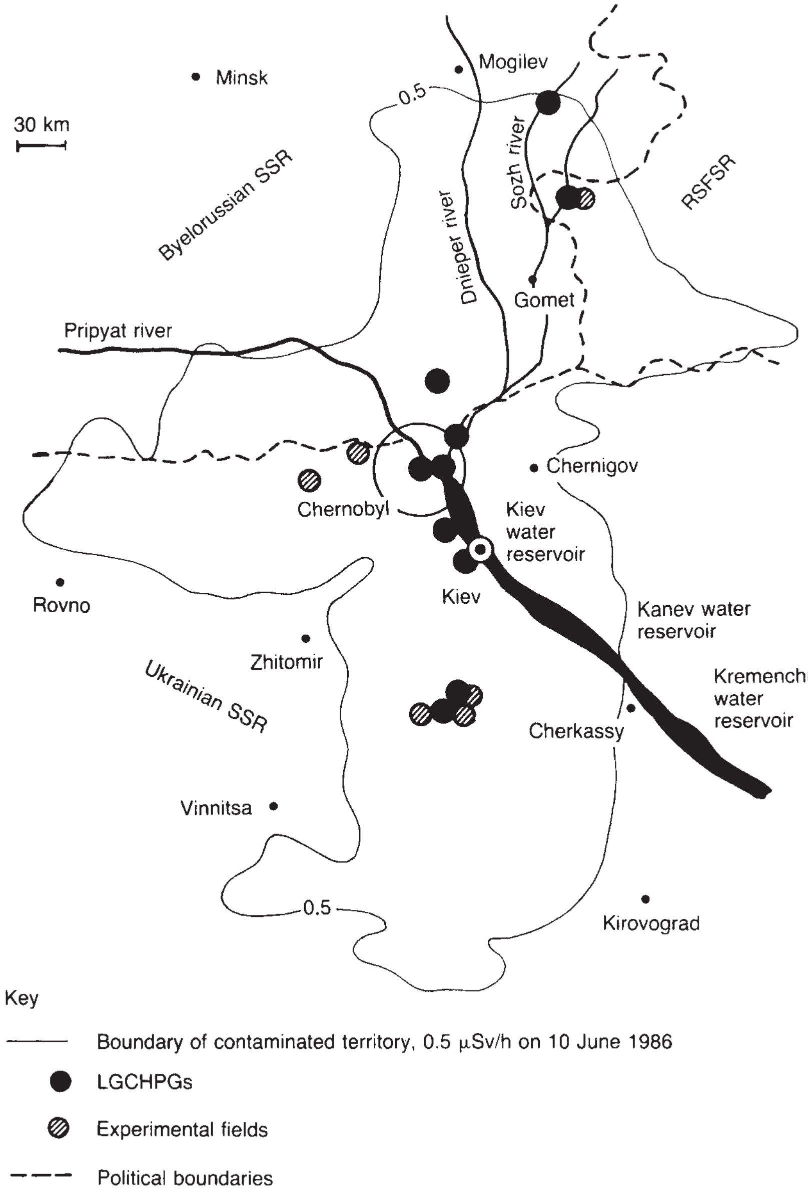

Figure A22.3 *Evacuation Zone and Contamination Zone around Chernobyl site (after Watt Committee, 1991)*

station into the space beneath the reactor vault. This reduced the oxygen concentration and the temperature. By 6 May the temperature rise had been halted and the temperature began to decline.

Meanwhile Soviet experts were concerned about the hazard of the large amount of water directly beneath the reactor. If the core were to come into contact with this water, there could be massive and explosive vaporization into steam. Engineers went down through dark passages flooded with radioactive water and succeeded in opening two large valves to allow the water to drain out.

Next an attempt was made to put a large concrete slab fitted with cooling coils beneath the core to prevent material from the core contaminating the ground and watercourses beneath it. Tunnelling in the soil at this point was difficult and it was necessary to resort to freezing the soil using liquid nitrogen, a method used in building the Leningrad Metro. The construction of this concrete bed was complete by the end of June.

Subsequently the reactor was entombed in concrete.

There was also intense activity to counter the effects of radioactivity in the surrounding area. 7000 wells were sealed. The water supply to Kiev could no longer be taken from water near the plant and a new water supply for the city had to be constructed. A system of dikes was constructed to catch radioactive rain water from the area around the plant. A system of bore holes and barriers was created to prevent contamination of water courses.

Decontamination measures were also set in train. The site itself was divided into zones. The measures taken were to remove debris and contaminated equipment, decontaminate roofs and outer surfaces of buildings, remove a 5–10 cm layer of soil into containers, lay where necessary concrete or fresh earth on the ground, and coat certain surfaces with film-forming compounds.

Decontamination of the area outside the site was complicated by the fact that the distribution of the radionuclides changed with time according to the terrain, particularly during the first 3–4 months. Hence the full value of measures to decontaminate a particular area is generally obtained only temporarily. Buildings were hosed down and the earth around them then removed. Measures were developed to allow the contaminated land to be used for agriculture: these included changes to methods of cultivation and harvesting and the use of dust-suppression materials.

The accident was the subject of intense press interest world-wide, although hard facts were difficult to come by. Interest centred on satellite photographs of the burning core, evacuation measures taken or not taken, the assistance given by an American bone marrow transplant surgeon, potential fallout in other countries and implications for nuclear power generally.

The fire in the reactor was readily seen from above and satellite photographs appeared on the world's television screens. These were soon supplemented by Soviet pictures of the stricken reactor.

The death toll from Chernobyl cannot be known with certainty, since most deaths will be excess cancers. Two men died dealing with the accident itself. By the end of September the toll of dead in the USSR was 31 with 203 injured. The casualties are discussed further in Section A22.8.

Other European countries were also affected. Radioactive contamination was measured across Europe and many countries banned particular products for a period.

A22.7 The Investigations

A22.7.1 USSR State Committee Report

In the West the main source of information on the accident was initially the investigation described in the *USSR State Committee Report.*

Part I of the report gives a brief description of the reactor and describes the accident itself. The seven appendices of Part II describe the reactor system, the detailed design of the reactor, the measures to deal with the consequences, the quantity of radioactivity released, the dispersion of the radioactive plume and the radioactive deposition, the radio-ecological contamination caused, and the medical and biological consequences.

An important feature of the investigation was a simulation of the accident using a mathematical model. This was assisted by the fact that the control computer had a program which logged several hundred critical parameters with a minimum cycle time of 1 s.

According to the simulation a power surge occurred in the reactor which took the output to 530 MWt within 3 s. There was intense steam formation and then nucleate boiling in the fuel channels and abrupt pressure increase, causing bursting of the channels.

The primary explosion was therefore bursting of the fuel channels by high pressure steam. The formation of steam and the rapid rise in core temperature created conditions for the steam–zirconium and other reactions. These reactions gave rise to hydrogen and carbon monoxide. After the reactor space had been vented and destroyed these mixed with air and burnt causing an explosion.

The report criticises both the experimental programme and the conduct of the test. It states

> The quality of the programme was poor and the section on safety measures was drafted in a purely formal way. . . Apart from the fact that the programme made essentially no provision for additional safety measures, it called for shutting off the reactor's emergency core cooling system.
>
> Because the question of safety in these experiments had not received the necessary attention, the staff involved were not adequately prepared for the tests and were not aware of the possible dangers. Moreover, as we shall see in what follows, the staff departed from the programme and thereby created the conditions for the emergency situation.

The report highlights the positive void coefficient as a problem feature of the reactor design. It lists six violations of the operating instructions by the operators and gives the motivation for and consequences of each.

The test programme specified that the ECCS should be disconnected. In addition, the reactor shut-down trip based on turbogenerator shut-down was disarmed. During the actual test the reactor shut-down trip based on coolant parameters was disarmed. These three actions were all taken to facilitate the test. The three other violations were the reduction in the reactivity margin, the switch from local automatic power control to manual control and the switching on of the standby pumps. The first was connected with attempts to deal with the poisoning problem and it rendered the protective system ineffective. The second was an operator error and it made the reactor much more difficult to control. The third was done to make doubly sure of adequate cooling and it resulted in loss of level in the separator and the decision to disable the reactor shut-down trip based on coolant parameters.

The report also points out that at low power levels the measurement of power density in the core is less accurate.

The report gives an account of the release from the damaged reactor and of the emergency measures taken.

The report records a number of measures being taken to prevent a repetition. They include changes to the organization responsible for the reactors and to the inspection organization and intensification of research on safety aspects.

An important design modification mentioned is the use of uranium fuel enriched to 2.4% rather than 2% in order to try to avoid the positive void coefficient problem.

In presenting the report to the IAEA Legasov is reported as saying that the plant was one of the best in the country with good operators who were so convinced of its safety that they 'had lost all sense of danger'.

A22.7.2 Other reports

As described at the start of the section, there have been a number of other reports on Chernobyl. The coverage of these reports is broadly as follows:

A22.8 The Release – 2

Estimates of the amount of radiation released are given in the *USSR State Committee Report* and several of the other reports mentioned. Table A22.3 Section A, based on figures given by Konstantinov and Gonzalez (1989), gives one such estimate of the total release, while Section B, based on the *USSR State Committee Report*, gives an estimate of the rate of release, showing the fall-off after 6 May.

According to the *USSR State Committee Report*, on 26 April the area around the site was in a low gradient pressure field with a slight wind varying in direction. At an altitude of about 1 km the wind speed was 5–10 m/s in a north-westerly direction.

The most intense plume observed was during the first 2–3 days in a northerly direction. Radiation levels in this stream at 5–10 km from the reactor and at 200m altitude were 1000 mR/h on 27 April and 500 mR/h on 28 April. According to aircraft monitoring data on 27 April the height of the stream exceeded 1200m in a north-westerly direction and the radiation level at this height was 1 mR/h. During the following days the height of the stream did not exceed 200–400 m.

Information on the radiation levels experienced at and around the site is patchy. The report states that those at the site exceeded 100 mR/h. The report also gives the following additional activities:

15 days after the accident at 30–40 km north: 35–40 mR/h
15 days after the accidents at 50–60 km west: 5 mR/h
At beginning of May in Kiev: 0.5–0.8 mR/h

Maps of the radioactive fallout in the Chernobyl region are given in the Second Watt Committee Report and by Read. Figure A22.3 from the former shows the boundary of the zone contaminated to the level of 0.5 μ Sv/h on 10 May 1986.

Accounts and maps of the radiation dispersion patterns over Europe and over the United Kingdom are given in the *UKAEA Report* and in the two *Watt Committee Reports* and by Apsimon and Davison (1986), Wheeler *et al.* (1989) and Hass *et al.* (1990).

Figure A22.4 from Gittus *et al.* (1987) shows the estimated radiation dispersion pattern across Europe on 3 May 1986.

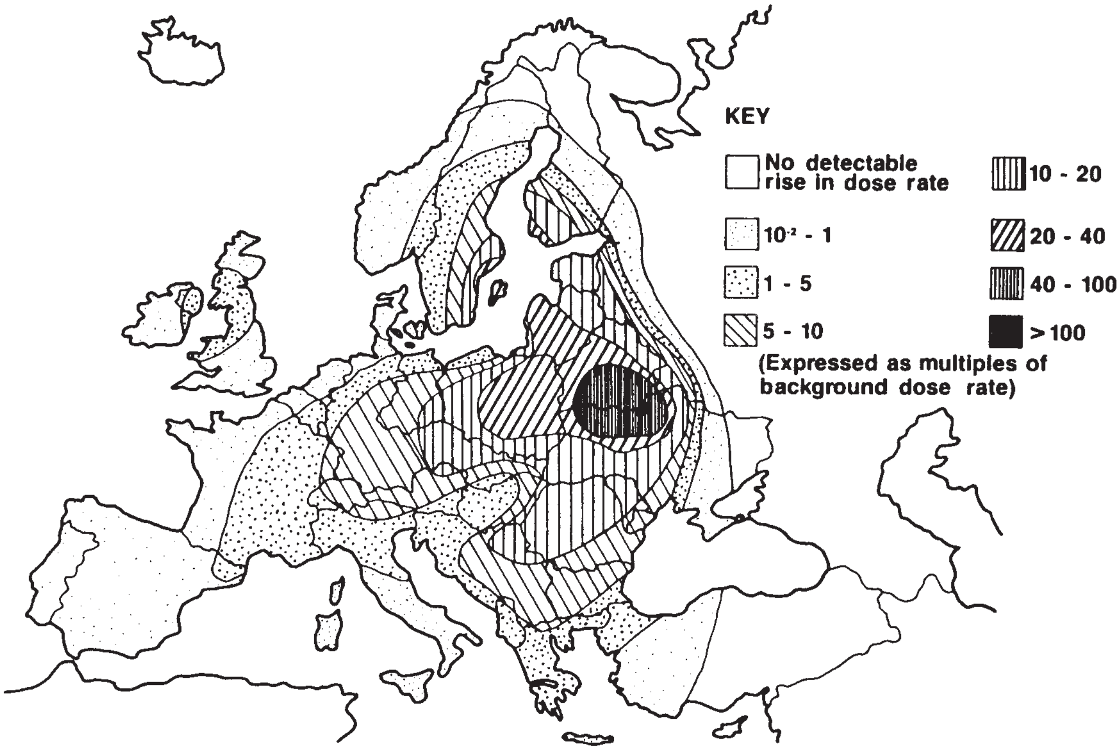

Figure A22.4 *Radiation dispersion pattern across Europe 3 May 1986 (Gittus et al., 1987)*

According to the Second *Watt Committee Report*, of the 4% of the core inventory dispersed, the distribution was approximately 0.3–0.5% on the reactor site, 1.5–2.0% within 20km and 1.0–15% beyond 20 km. The most significant isotopes outside the USSR were I-131, Cs-134 and Cs-137.

In Europe the highest dose equivalents in the year after the accident were 0.76, 0.67 and 0.59 mSv in Bulgaria, Austria and Greece, respectively, while that in the United Kingdom was 0.03 mSv.

A22.9 The Later Aftermath

Of those on site at the time, two died on site and a further 29 in hospital over the next few weeks. A further 17 are permanent invalids and 57 returned to work but with seriously affected capacity. The others on site, some 200, were affected to varying degrees. There is apparently no detailed information on the effects on the military and civilian personnel brought in to deal with the accident.

Potential health effects at relatively low doses are discussed in Appendix 20. A detailed discussion of such effects from Chernobyl is given in the Second *Watt Committee Report*. For EC countries the estimates of the NRPB in 1986 were 100 fatal thyroid cancers and 2000 fatal general cancers, or 2100 fatal cancers. For the USSR the situation is much more complex, but the report quotes an estimate by Ryin *et al.* (1990) of 1240 fatal leukaemia cases and 38,000 fatal general cancers.

Table A22.4 *Some lessons of Chernobyl*

Management of, and safety culture in, major hazard installations
Adherence to safety-related instructions
Inherent safer design of plants
Sensitivity and operability of plants
Design of plant to minimize effect of violations
Disarming of protective systems
Planning and conduct of experimental work on plants
Accidents involving human error and their assessment
Emergency planning for large accidents
Mitigating features of accidents

Measures to reduce the hazard from Unit 4 reactor have continued long after the events described, involving devoted and heroic work to limit the harm to their fellows, not only in the USSR but elsewhere.

A22.10 Some Lessons of Chernobyl

Some of the lessons of Chernobyl apply specifically to the nuclear industry and these are not considered here, but the more important ones are equally applicable to the process industries. A list of some of these is given in Table A22.4 These lessons are now considered.

A22.10.1 Management of, and safety culture in, major hazard installations

The management of the organization at the Chernobyl plant were clearly inadequate for the operation of a major hazard installation.

The defects highlighted particularly in the foregoing account are a weak safety culture and overconfidence, a potentially lethal combination.

A22.10.2 Adherence to safety-related instructions

Closely linked to this is the lesson which most commentators have highlighted as the principal one, the need to adhere to safety-related instructions. At Chernobyl a number of such instructions were violated by the operators. These violations included disconnecting the ECCS and disabling two sets of trip systems.

A22.10.3 Inherently safer design of plants

The Chernobyl reactor had a low degree of inherent safety, due particularly to the positive temperature coefficient.

The reactor did have some features, however, which might be claimed to be inherently safer. Thus by avoiding the use of a single large pressure vessel the design eliminated the hazard of catastrophic rupture of such a vessel and by subdividing the fuel into individually cooled channels it reduced the risk of total core meltdown.

On the other hand in addition to the sensitivity inherent in the positive temperature coefficient, the design also involved massive graphite blocks which could burn.

Chernobyl thus also illustrates the fact that inherently safer design does not have a single dimension, but is multidimensional.

A22.10.4 Sensitivity and operability of plants

Closely related to inherently safer design is the sensitivity and operability of plants. The nuclear reactor at Chernobyl had a regime, that of low excess reactivity, at which it was close to instability and difficult to control. This is an undesirable characteristic in any plant. This fact is recognized in the recommendation made that the uranium fuel enrichment be increased to 2.4%.

A22.10.5 Design of plant to minimize effect of violations

At Chernobyl it was necessary to avoid operating the plant with a power output less than 20% of the rated value. Where there is a feature which is so critical, it is arguable that the plant should be designed to ensure that it cannot be violated. This is another aspect of inherently safer design.

The practicality of such an approach can only be decided in the light of the particular case. As Franklin argues, it is not practical to design against all conceivable violations.

A22.10.6 Disarming of protective systems

The disarming of protective systems is a permissible practice in certain cases, but these need to be well defined and there must be proper procedures for doing so. At Chernobyl, protective systems were disarmed which should not have been.

A22.10.7 Planning and conduct of experimental work on plants

When work is to be done on a plant, whether engineering work or experimental testing, it is necessary, particularly if the work involves modification to safety-related features such as the disarming of trips, to review the potential hazards and to have specific authorized arrangements for the safe operation of the plant.

Once the test is under way, unauthorized modifications should not be made to the equipment or to the test procedure itself which have potential safety implications.

A22.10.8 Accidents involving human error and their assessment

The Chernobyl disaster was caused by a series of actions by the operators of the plant. It appears to be a case of human error which is virtually impossible to foresee and prevent. No doubt the probability of any one of the events would have been assessed as low and that of their combination is virtually incredible. But there was a common factor, namely the determination to carry out the test.

There is a need for the development of techniques, both for design and for hazard assessment of plant, for identifying potentially hazardous operator intervention sequences.

A22.10.9 Emergency planning for large accidents

The scale of the accident at Chernobyl was such that the resources required to deal with the emergency exceeded those available locally. In the event, the authorities responded by mobilizing resources on a military scale. Large numbers of military and civilian personnel were drafted in to work on the reactor itself, on evacuation and on decontamination. The evacuation on 27 April required some 1000 buses.

A22.10.10 Mitigating features of accidents

In terms of the effect of the accident on the population near the site there were several factors which mitigated the effect of the accident at Chernobyl, although the full value of these was partially lost due to hesitation in carrying out the evacuation. These mitigating features are discussed by Hawkes *et al.* (1986).

The accident occurred at night so that fewer people were exposed on site and the population outside were mostly indoors. The intense fire created the conditions for the radioactive plume to rise high and carry the release away. There was little wind so that the plume was not prevented from rising and such wind as existed was away from the large centres of population to the south. The weather was dry so that the radioactivity was not washed down on the nearby population.

Appendix

23

Rasmussen Report

Contents

A comprehensive hazard assessment of nuclear power plants in general is the *Reactor Safety Study: An Assessment of Accident Risks in US Commercial Nuclear Power Plants* by the Nuclear Regulatory Commission (NRC) (1975). The work was done by a team led by Professor N.C. Rasmussen and is often referred to as the *Rasmussen Report*. It is also known as the *Reactor Safety Study* (RSS) and also as *WASH 1400*. It is referred to in this appendix as the *Reactor Safety Study* but elsewhere as the *Rasmussen Report*.This study was a major exercise involving some 70 man years of work and costing $4 million. The report is a document of nine volumes some 15 cm thick.

The RSS constituted a watershed in probabilistic risk assessment. It not only brought the PRA approach to the fore as an aid in decision-making, but created a framework and brought together the various techniques needed to carry out such a study.

The work is of interest in respect of its methodology, its treatment of particular problems in risk assessment, its compilations of failure data and its presentation and evaluation of risks. Also of interest are the critiques of the report.

The methodology is based on the extensive use of fault trees and event trees and addresses the problem of uncertainty in the results obtained.

The report has been followed by further reports which have developed the methodology. In particular, a treatment of overall PRA methodology is given in the *PRA Procedures Guide* of the NRC (1982) and of human factors methodology in the *Handbook of Human Reliability Analysis with Emphasis on Nuclear Power Plant Applications. Final Report* by Swain and Guttmann (1983).

Selected references on the *Reactor Safety Study* are given in Table A23.1.

A23.1 Earlier Studies

The *RSS*, or *WASH 1400*, was not the first study of this subject. There were several earlier reports on nuclear reactor safety.

The first of these was the report *Theoretical Possibilities and Consequences of Major Accidents in Large Nuclear Power Plants* by the Atomic Energy Commission (AEC) (1957). The work was done by the Brookhaven National Laboratory and is often referred to as the Brookhaven Report and also as *WASH 740*.

WASH 740 considered as a pessimistic accident scenario, or maximum credible accident, a situation where a reactor was nearing time for refuelling and thus contained its largest inventory of fission products and suffered an accident involving loss from containment of half the core inventory in weather conditions which would carry the cloud towards a town of one million people 50 km away. It was estimated that this accident could result in 3,400 deaths, 43,000 injured and $7 billion property damage.

Table A23.1 Selected references on the Reactor Safety Study

Earlier studies
AEC (1957); Ford (1977)

Reactor safety study
AEC (1975)

Reviews and critiques
AEC (1975) (Appendix XI); EPRI (1975); Hocevar (1975); Leverenz and Erdmann (1975, 1979); Boffey (1976); EPA (1976); Yellin (1976); Erdmann *et al.* (1977); Ford Foundation and Mitre Corp. (1977); UCS (1977); H.W. Lewis (1978); S. Levine (1978, 1979); ANS (1980); Hanks (1986)

The report did not give an estimate of the frequency of such an event and stated in effect that the methodology to do so did not exist.

A study to update *WASH 740* was carried out by Brookhaven National Laboratory. The study was essentially complete by 1965 but was published only in 1973. It considered an even more pessimistic scenario of a large accident in a city and gave estimates of 45,000 deaths and 70,000 injuries.

Another report on reactor safety was *The Safety of Nuclear Power Reactors (Light Water Cooled) and Related Facilities* by the AEC (1973), or *WASH 1250*. This report included both accounts of policy and collections of data and contained some of the early results of WASH 1400.

A23.2 Risk Assessment Methodology

The report provides a framework for probabilistic risk assessment. The overall methodology described is based on selection of a set of release scenarios; estimation of the frequency of each scenario using fault trees and of the frequency of each associated set of outcomes using event trees; estimation of the consequences using hazard models for the physical phenomena and models of population exposure, mitigation of exposure by shelter and by escape and evacuation and injury from radioactivity and evaluation of these results using risk criteria. Table A23.2(A) indicates the subjects covered by the various volumes of the report and Table 23.2(B) some of the specific topics. Reference to the report is frequently made here, in particular with respect to (1) failure and event data; (2) lognormal distribution; (3) fault trees; (4) event trees; (5) common mode failure; (6) human error; (7) evacuation; (8) shelter; (9) FN curves and (10) risk evaluation.

The *RSS* gives risk assessments of both PWRs and BWRs, but the account given here is largely confined to the former.

A23.3 Event Data

The *RSS* contains a compilation of a large amount of failure and event data. These are based primarily on nuclear industry experience supplemented by other sources.

Most of the data refer to 2 years' experience at 17 nuclear plants which were operational in the United States in 1972. The average plant in the sample was some 4 years old.

Data for equipment are given as failure rates or probabilities of failure on demand.

It is assumed that the failures are random and that the exponential failure distribution is applicable. The possibility of failure due to ageing was considered but excluded. The report states:

> It should be recognized that the study did not include extreme ageing consideration since the applicability of its results is limited to only the next five years.

The data on failure rates and probabilities are given not as point values but as ranges. Most of these data are presented in terms of the 90% confidence range and are

correlated using the log–normal distribution with values quoted for the lower and upper bounds, median and error factor. This use of the lognormal distribution reflects the large amount of uncertainty in the data so that for many items it was possible to give only order of magnitude values for the failure rate or probability.

It is convenient to use as one of the parameters which describe the log–normal distribution the median. The report therefore quotes median values for much of the data.

In addition to data on failures, data for test and repair times are also given. These times are also correlated using the log–normal distribution.

It is worth emphasizing that in the report the lognormal distribution is not used to correlate times to failure. These are assumed to be exponentially distributed so that they are described by a constant failure rate. The lognormal distribution is used to describe the spread of these failure rates. On the other hand the log–normal distribution is indeed used to characterize test and repair times.

There are special studies of pipework failure and power supply failure. Reactor pressure vessel failure is also considered.

Some of the failure and event data in the *RSS* are given in Appendix 14.

A23.4 Fault Trees

The *RSS* makes extensive use of fault trees. The need to do this arises because the accident events considered can occur only if there are failures of a number of protective systems and because such failures are rare and insufficient historical data for them are available.

The volume of the report which deals with the fault trees contains some 150 figures, most of them fault tree diagrams.

The computer codes PREP and KITT were used to calculate the frequencies of the top events from those of the base events.

The PWR function unavailabilities obtained from the fault tree analyses are summarized in Table A23.3.

A23.5 Event Trees

The basic accident sequence considered is an initiating event followed by system failure and then containment failure.

The *RSS* makes extensive use of event trees for the accident sequences.

A summary of the event trees is given in Table A23.4.

A23.6 Common Mode Failure

Common mode failures are recognized in the *RSS* as a factor which may greatly increase the frequency of the hazard.

Several techniques are used to handle such common mode failures. For similar events which may in some way be coupled, such as human actions to calibrate an instrument or open a valve, lower and upper bound probabilities of failure are defined. The lower bound probability p_l is the probability calculated assuming complete independence of the events. The upper bound probability p_u is the probability calculated assuming complete coupling between the events. The actual probability p is then taken as the geometric mean, or log–normal median

$$p = (p_l p_u)^{1/2} \quad [A23.6.1]$$

The example given is the reclosing of two valves. The probability of failing to close one valve is taken as 10^{-2}. Then, the lower bound is 10^{-4} $(10^{-2} \times 10^{-2})$ and the upper bound 10^{-2} $(10^{-2} \times 1)$, while the probability given by Equation A23.6.1 is 10^{-3} $((10^{-4} \times 10^{-2})^{1/2})$.

The method of handling coupled events in a fault tree is described below.

Other common mode failures may occur as the result of a common event such as a fire or earthquake. The treatment of such external threats is considered below.

The *RSS* concludes that common mode failures do not make a large contribution to the overall frequency of core melt failure.

A23.7 Human Error

The report gives an extensive treatment of human error and estimates for error rates for a number of types of error. It also deals with problems such as non-independence of, or coupling between, errors.

The treatment of human error in the *RSS* and the *Handbook of Human Reliability Analysis* are described in Chapters 9 and 14 and some of their error rate estimates given.

A23.8 Rare Events

An important rare event considered in the *RSS* is failure of the reactor pressure vessel. The report states

Potentially large ruptures in the vessel were considered that could prevent effective cooling of the core by the ECCS. Since certain of these ruptures appeared to be capable of causing missiles (such as the reactor vessel head) with sufficient momentum to rupture the containment, this area was explored with some care. There is some small probability that a large vessel missile could in fact impact directly on the containment and penetrate through the wall. This type of rupture could involve a core meltdown in a non-intact containment.

A study by the Advisory Committee on Reactor Safeguards (ACRS) concluded that 'the disruptive failure probability of reactor vessels designed, constructed and operated according to code is even lower than 1×10^{-6} per vessel year.' The figure used in the *RSS* is 1×10^{-7}/vessel year.

The effect of this low estimate of reactor pressure vessel failure rate is to take this event out of consideration as a cause of release. The *RSS* states

> Gross vessel rupture would have to be at least about 100 times more likely than the value estimated in order to contribute to the PWR core melt probability.

A23.9 External Threats

The *RSS* considers external threats such as fire, earthquakes and sabotage.

The prediction of earthquakes is highly uncertain and the report emphasizes this. It nevertheless states that a 'reasonable estimate (of core melt due to earthquake) is 10^{-7} per reactor year'.

The *RSS* acknowledges the threat posed by sabotage, but does not take this into account in the risk estimates made. These estimates apply to bona fide accidents and exclude those due to sabotage.

Table A23.3 *Reactor Safety Study: PWR function unavailabilities from trees (Nuclear Regulatory Commission, 1975)*

System	*Unavailability* (Q)			*Major contributors* (point estimates)

[a] Also human error.

[b] Containment pressure must be reduced to $<\frac{1}{2}$ psi to isolate containment spray injection system.

[c] Common mode resulting from human error.

[d] Point estimate value obtained only.

NA, not applicable to combined systems.

Table A23.4 *Reactor Safety Study: PWR accident sequences from event trees (Nuclear Regulatory Commission, 1975)*

Symbol	*Meaning*
A	Intermediate to large LOCA
B	Failure of electric power to ESFs
B′	Failure to recover either on-site or off-site electric power within about 1 to 3 h following an initiating transient which is a loss of off-site a.c. power
C	Failure of the containment spray injection system
D	Failure of the emergency core cooling injection system
F	Failure of the containment spray recirculation system
G	Failure of the containment heat removal system
H	Failure of the emergency core cooling recirculation system
K	Failure of the reactor protection system
L	Failure of the secondary system steam relief valves and the auxiliary valves and the auxiliary feedwater system
M	Failure of the secondary system steam relief valves and the power conversion system
Q	Failure of the primary system safety relief valves to reclose after opening
R	Massive rupture of the reactor vessel
S_1	A small LOCA with an equivalent diameter of about 5–15 cm
S_{12}	A small LOCA with an equivalent diameter of about 1–5 cm
T	Transient event
V	Failure of low-pressure injection system check valve
α	Containment rupture due to a reactor vessel steam explosion
β	Containment failure resulting from inadequate isolation of containment openings and penetrations
γ	Containment failure due to hydrogen burning
δ	Containment failure due to overpressure
ε	Containment vessel melt-through

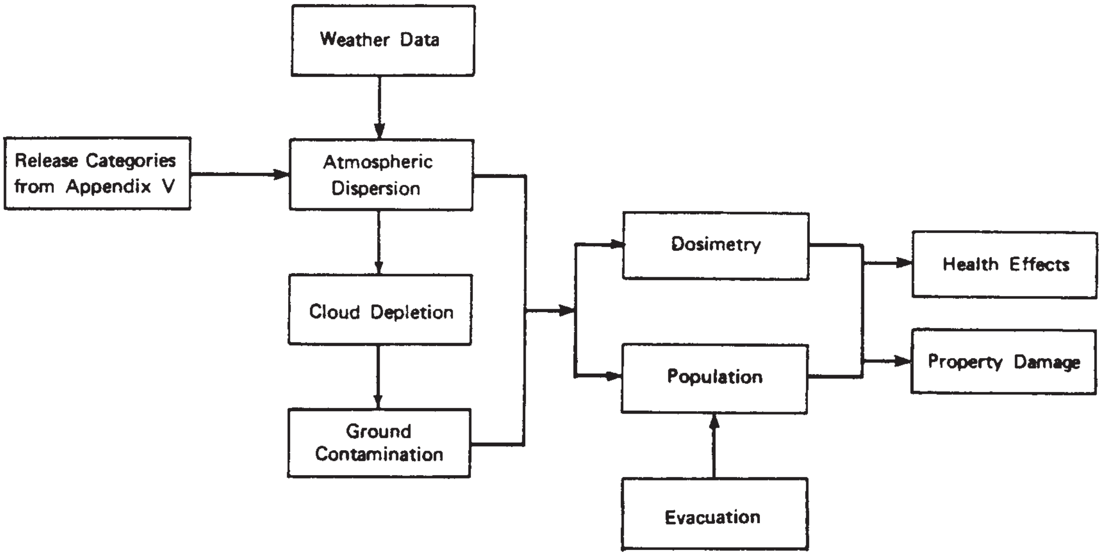

Figure A23.1 *Reactor Safety Study: Schematic outline of consequence models (Nuclear Regulatory Commission 1975)*

A23.10 Release Scenarios

The consequences of a core degradation or meltdown depend on (1) core inventory; (2) fraction released; (3) dispersion and deposition; (4) population exposed; (5) mitigating features (evacuation, shelter); and (6) injury relations.

A schematic outline of the consequence models is shown in Figure A23.1.

The initial radioactivity of the radionuclides in the reactor core is given in Table A23.5 and the reactor core inventory in Table A23.6.

The release scenarios are shown in Tables A23.7 and A23.8.

The release from the reactor is used in the report as the source term for a plume gas dispersion model. This model takes into account the deposition of solid radionuclides.

A23.11 Population Characteristics

The population at risk was characterized by a composite model based on the 68 actual sites holding the first 100 reactors. Six composite sites of different types were defined.

The population density was determined as follows. The first type of site was an Atlantic coastal site and 14 of the reactors were assigned to this composite site. The actual population around each of these reactors was determined from census data for a distance of 50 miles. For each actual site 16 sectors were defined, making 224 sectors in total. These 224 sectors were then ranked in order of population density and 16 representative sectors were determined for the composite site.

Data from a time use study by J.P. Robinson and Converse (1966) were used to determine the fraction of time spent at different locations and hence the probability that a person was inside shelter.

A23.12 Mitigation of Exposure

Factors which mitigate the exposure of the population include shelter and evacuation.

The *RSS* uses a single exponential stage evacuation model. This model is based on a study of actual evacuations by Hans and Sell (1974).

Measures to mitigate long-term exposure include interdiction of the contaminated zone and decontamination of this zone.

The effect of shelter on concentration is modelled using a single exponential stage model for ventilation.

A23.13 Injury Relations

The effects of radioactivity on people are complex and are both short-term, or prompt, and long-term.

Table A23.6 *Reactor Safety Study: reactor core inventory (Nuclear Regulatory Commission, 1975)*

Location	*Total inventory* (curies)			*Fraction of core inventory*		
	Fuel	*Gap*	*Total*	*Fuel*	*Gap*	*Total*
Core[a]	8.0×10^9	1.4×10^8	8.1×10^9	9.8×10^{-1}	1.8×10^{-2}	1
Spent fuel storage pool (max.)[b]	1.3×10^9	1.3×10^7	1.3×10^9	1.6×10^{-1}	1.6×10^{-3}	1.6×10^{-1}
Spent fuel storage pool (av.)[c]	3.6×10^8	3.8×10^6	3.6×10^8	4.5×10^{-2}	4.8×10^{-4}	4.5×10^{-2}
Shipping cask[d]	2.2×10^7	3.1×10^5	2.2×10^7	2.7×10^{-3}	3.8×10^{-5}	2.7×10^{-3}
Refuelling[e]	2.2×10^7	2×10^5	2.2×10^7	2.7×10^{-3}	2.5×10^{-5}	2.7×10^{-3}
Waste gas storage tank	–	–	9.3×10^{-4}	–	–	1.2×10^{-5}
Liquid waste storage tank	–	–	9.5×10^1	–	–	1.2×10^{-8}

[a] Core inventory based on activity 1/2 h after shutdown.
[b] Inventory of 2/3 core loading; 1/3 core with 3 day decay and 1/3 core with 150 day decay.
[c] Inventory of 1/2 core loading; 1/6 core with 150 day decay and 1/3 core with 60 day decay.
[d] Inventory based on 7 PWR or 17 BWR fuel assemblies with 150 day decay.
[e] Inventory for one fuel assembly with 3 day decay.

In order to determine these effects it is first necessary to estimate the doses of radioactivity received and then to apply a dose–response relation.

The *RSS* gives a detailed treatment of all these aspects and the report contains a large number of tables and graphs showing early and late fatalities and injuries due to different modes of injury and the contribution to these of individual radionuclides.

It also deals with the contamination of land.

A23.14 Uncertainty in Results

An attempt is made in the report to put bounds on the errors of the estimates.

A number of methods are used. Failure rates and probabilities are taken not as single values but as a range of values with a lognormal distribution, as described above.

The inputs to the fault trees are therefore not single values of frequency or probability but distributions of these. The frequency or probability of the top event is then computed, also as a distribution, by sampling from the distributions of these individual events using Monte Carlo simulation.

Such simulation may also be used to take account of common mode failures by arranging coupling between the failure rates or probabilities in question.

A23.15 Presentation of Results

The risks from reactor accidents are presented in the main report principally in the form of tables of frequency–consequence results.

The results for 100 reactors are for the mix of both PWR and BRW reactors considered in the study. The risks for an individual PWR are higher than for a BWR and those for a composite single reactor based on the mix are close to those for a PWR.

Table A23.9(A) shows the societal risk of early effects from one reactor and Table A23.9(B) of those from late effects. The report gives another table showing the societal risk from 100 reactors, the frequencies simply being greater by a factor of 100. Table A23.10 shows the individual and average societal risk from 100 reactors.

The results are also given in graphical form. Figure A23.2 gives a histogram of PWR release categories. Figure A23.3 is the frequency–consequence curve, or FN curve, for early fatalities from a single reactor. The graph shows curves for a PWR, a BWR and the composite reactor.

Figure A23.4 is the frequency–consequence curve for areas in which relocation of people and decontamination would be required.

A23.16 Evaluation of Results

The *RSS* evaluates the risk from the 100 nuclear reactors by making comparisons with those from other hazards.

The main report gives numerous tables showing risks from various natural and man-made hazards such as earthquakes, hurricanes, tornadoes, meteorites, fires, dams, explosions, toxic gas releases and aircraft crashes.

One of the principle comparisons made is the FN curve for the 100 reactors and for other hazards. Figures A23.5 and Figure A23.6 show, respectively, the FN curve for early deaths for natural hazards and for man-made hazards together with the curve for 100 reactors.

The overall conclusion of the report is that the risks to the public from 100 nuclear reactors are very much less than those from other natural and man-made hazards.

The report has a slim Executive Summary which describes the report as a whole and gives a presentation and evaluation of the results. This summary does not include the societal risk estimates given in Table A23.9 and in general tends both to play down the risks and gloss over many qualifying assumptions.

A23.17 Browns Ferry Incident

The incident at Browns Ferry is widely regarded as a near miss and the *RSS* could hardly avoid reference to this incident.

On 22 March 1975 a fire started in the electrical control cables at the plant. Following a plant modification a candle was used to detect air leaks at a point where a set of electrical cables passed through a wall. The fire burned out of control for $7\frac{1}{2}$ hours and badly damaged 1600 cables of which 618 were cables related to the safety systems.

The power interruption caused disturbances on the reactors and the operators, hindered by dense smoke, had to struggle to bring them back under control. Unit 2 was shut-down and stabilized without great difficulty but Unit 1

Table A23.7 *Reactor Safety Study: PWR release scenarios ±1 (Nuclear Regulatory Commission, 1975)*

					Fraction of core inventory released						
Accident category and frequency f_j	*Description of accident category*	*Duration of release* (h)	*Elevation of release* (m)	*Energy release rate* (Btu/h)	*Xe–Kr*	*I*	*Cs = Rb*	*Te–Sb*	*Ba–Sr*	*Ru, Rh, Co, Mo, Tc*	*Y, La, Zr, Nb, Ce, Pr, Nd, Np, Pu, Am, Cm*
PWR1a and 1b 9×10^{-7} per year	Core melt-down and failure of containment spray and heat removal systems 1a – steam explosion after containment failure due to overpressure; 1b – steam explosion ruptures containment	0.5	25	20×10^{6}(1a) 520×10^{6}(1b)	0.9	0.7	0.4	0.4	0.05	0.4	3×10^{-3}
PWR2 8×10^{-6} per year	Core meltdown, failure of containment spray and heat removal systems. Containment fails through overpressure after commencement of core meltdown	0.5	0	170×10^{6}	0.9	0.7	0.5	0.3	0.06	0.02	4×10^{-3}
PWR3 4×10^{-6} per year	Failure of containment due to overpressure before core meltdown	1.5	0	6×10^{6}	0.8	0.2	0.2	0.3	0.02	0.03	3×10^{-3}

PWR4 5×10^{-7} per year	Core meltdown and failure of containment system properly to isolate; failure of containment spray system	3.0	0	1×10^{6}	0.6	0.09	0.04	0.03	5×10^{-3}	3×10^{-3}	4×10^{-4}
PWR5 7×10^{-7} per year	As PWR4, but containment spray systems operate to reduce release to atmosphere	4	0	3×10^{-5}	0.3	0.03	9×10^{-3}	5×10^{-3}	10^{-3}	6×10^{-4}	7×10^{-5}
PWR6 6×10^{-6} per year	Core melt down, failure of containment sprays. Containment maintains integrity but core melts through base	10.0	0	0	0.03	8×10^{-4}	8×10^{-4}	9×10^{-8}	9×10^{-5}	7×10^{-5}	10^{-5}
PWR7 4×10^{-5} per year	As PWR6, but containment sprays operate	10.0	0	0	6×10^{-3}	2×10^{-5}	10^{-5}	2×10^{-5}	10^{-6}	10^{-6}	2×10^{-7}
PWR8 4×10^{-5} per year	Large pipe break, containment fails properly to isolate, all other engineered safeguards work, no core meltdown	0.5	0	0	2×10^{-3}	10^{-4}	5×10^{-4}	10^{-6}	10^{-8}	0	0
PWR9 4×10^{-4} per year	As PWR8, but all engineered safeguards function as designed. Essentially PWR design basis accident	0.5	0	0	3×10^{-6}	10^{-7}	6×10^{-7}	10^{-9}	10^{-11}	0	0

Table A23.8 *Reactor Safety Study: PWR release scenarios – 2 (Nuclear Regulatory Commission, 1975)*

Fission product	*Gap release fraction*	*Melthdown release fraction*	*Vaporization release fraction*[a]	*Steam explosion fraction*[b]
Xe, Kr	0.030	0.870	0.100	(X) (Y) 0.90
I, Br	0.017	0.883	0.100	(X) (Y) 0.90
Ca, Rb	0.050	0.760	0.190	–
Te[c]	0.0001	0.150	0.850	(X) (Y) (0.60)

Ru[d]	–	0.030	0.050	(X) (Y) (0.90)
La[e]	–	0.003	0.010	–

[a] Exponential loss over 2 h with half-time of 30 min. If a steam explosion occurs prior to this, only the core fraction not involved in the steam explosion can experience vaporization.
[b] X = fraction of core involved in the steam explosion. Y = fraction of inventory remaining for release by oxidation.
[c] Includes Se, Sb.
[d] Includes Mo, Pd, Rh, Tc.
[e] Includes Nd, Eu, Y, Ce, Pr, Pm, Sm, Np, Pu, Zr, Nb.

Table A23.9 *Reactor Safety Study: societal risk from one reactor (Nuclear Regulatory Commission, 1975)*

A Early effects

Chance per reactor-year	*Consequences*				
	Early fatalities	*Early illness*	*Total property damage* ($\$10^9$)	*Decontamination area* (≈square miles)	*Relocation area* (square miles)
One in 20,000[a]	<1.0	<1.0	<0.1	<0.1	<0.1
One in 1,000,000	<1.0	300	0.9	2,000	130
One in 10,000,000	110	3,000	3	3,200	250
One in 100,000,000	900	14,000	8	–	290
One in 1,000,000,000	3300	45,000	14	–	–

B Cancer and genetic effects

Chance per reactor-year	*Consequences*		
	Latent cancer[b] *fatalities* (per year)	*Thyroid nodules*[b] (per year)	*Genetic effects*[c] (per year)
One in 20,000[d]	<1.0	<1.0	<1.0
One in 1,000,000	170	1,400	25
One in 10,000,000	460	3,500	60
One in 100,000,000	860	6,000	110
One in 1000,000,000	1,500	8,000	170
Nuclear incidence	17,000	8,000	8,000

[a] This is the predicted chance of core melt per reactor year.
[b] This rate would occur approximately in the 10–40 year period following a potential accident.
[c] This rate would apply to the first generation born after a potential accident. Subsequent generations would experience effects at a lower rate.
[d] This is the predicted chance of core melt per reactor year.

was out of control for some hours and was stabilized only after the fire was put out. Control of Unit 1 was only achieved by the use of equipment which was not part of the safety system.

The fire disabled all five emergency core cooling systems in Unit 1.

At the point when control was lost 7 out of 11 of relief valves were failed. The fire disabled the other four. The *RSS* gives an analysis of the probability that these four valves would in fact be disabled in a fire without any of the valves, from the set of seven or the set of four, being repaired over the duration of the fire. The probability estimated was 0.003.

A23.18 Critical Assumptions

The results obtained in the *RSS* depend on the validity of a number of assumptions.

Some of the more critical assumptions are

plant standards are not seriously below average;
failures are random rather than wearout;
reactor pressure vessel operating conditions are closely controlled;
site is not subject to unusually severe earthquakes;
population density around site is not unusually high;
emergency plans exist and are exercised;

Table A23.10 *Reactor Safety Study: individual and average societal risk from 100 reactors (Nuclear Regulatory Commission, 1975)*[a]

Consequence	*Societal*	*Individual*
Early fatalities[b]	3×10^{-3}	2×10^{-10}
Early illness[b]	2×10^{-1}	1×10^{-8}
Latent cancer fatalities[c]	7×10^{-2} per year	3×10^{-10} per year
Thyroidnodules[c]	7×10^{-1} per year	3×10^{-9} per year
Genetic effects[d]	1×10^{-2} per year	7×10^{-11} per year
Property damage ($)	2×10^{6}	–

[a] Based on 100 reactors at 68 current sites.

[b] The individual risk value is based on the 15 million people living in the general vicinity of the first 100 nuclear power plants.

[c] This value is the rate of occurrence per year for about a 30 year period following a potential accident. The individual rate is based on the total US population.

[d] This value is the rate of occurrence per year for the first generation born after a potential accident: subsequent generations would experience effects at a lower rate. The individual rate is based on the total US population.

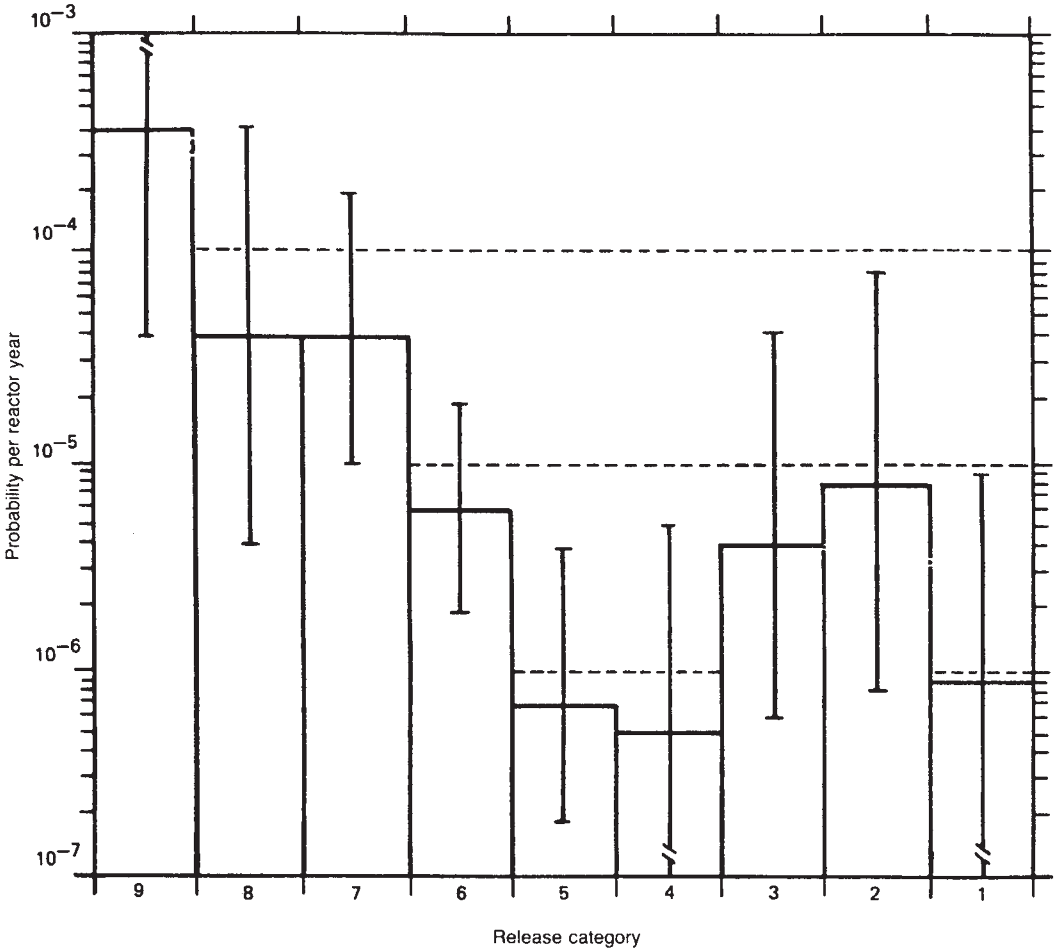

Figure A23.2 *Reactor Safety Study: histogram for frequency of PWR release categories (Nuclear Regulatory Commission, 1975)*

medical facilities exist to handle large numbers of injured; and also

sabotage is not considered.

A23.19 Critiques

The *RSS* has been the subject of much comment and criticism. Three principal critiques are the comments included as Appendix XI of the report itself, the *Risk Assessment Review Group Report* (H.K. Lewis, 1978) and *The Risks of Nuclear Power Reactors* by the Union of Concerned Scientists (UCS) (1977).

There are also reviews by the EPA (1976) and the American Nuclear Society (1980) and a series of reports by the Electric Power Research Institute (EPRI) (EPRI, 1975; Leverenz and Erdmann, 1975, 1979; Erdmann *et al.*, 1977).

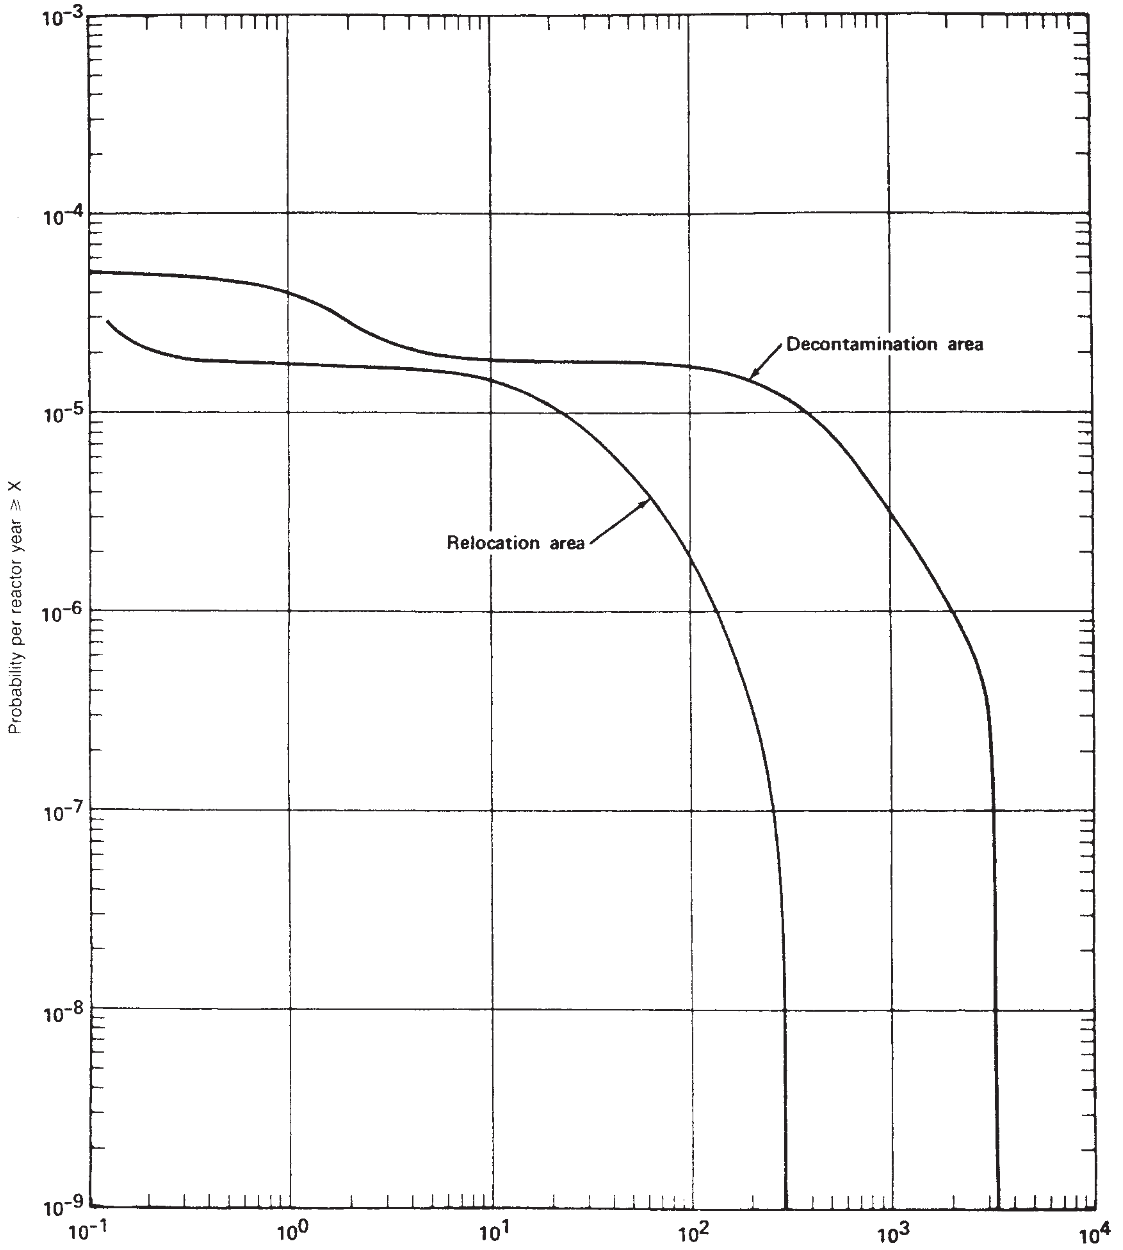

Figure A23.4 *Reactor Safety Study: frequency–consequence curve for areas requiring relocation and decontamination for one reactor (Nuclear Regulatory Commission, 1975)*

Some of the principal topics addressed in the critiques are indicated in Table A23.11.

Some of the comments made in the *Review Group Report* and the UCS review are now described.

A23.19.1 Review Group Report

The review found the *RSS* 'inscrutable'. It was difficult to follow the detailed thread of any calculation and difficult therefore to carry out a peer review.

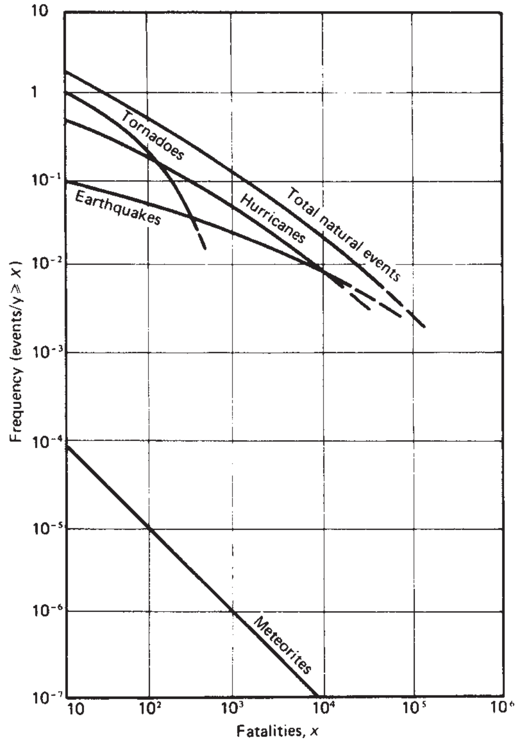

Figure A23.5 *Reactor Safety Study: FN curves for early fatalities for 100 reactors compared with natural hazards (Nuclear Regulatory Commission, 1975)*

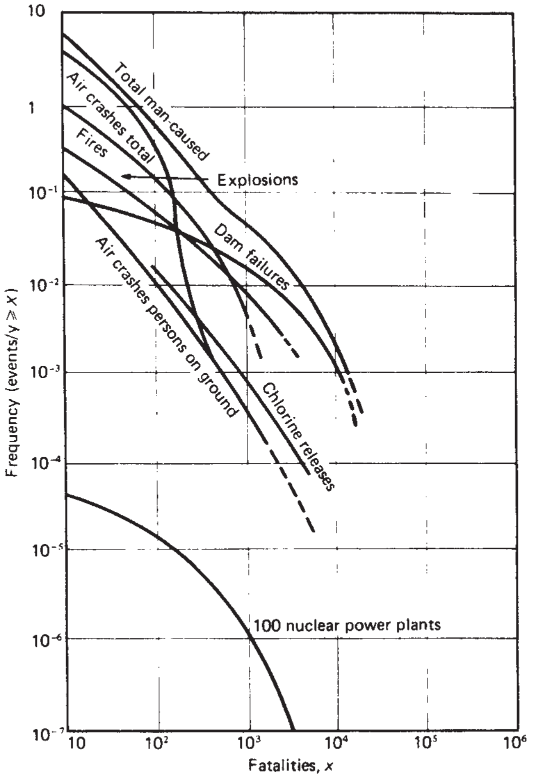

Figure A23.6 *Reactor Safety Study. FN curves for early fatalities for 100 reactors compared with man-made hazards (Nuclear Regulatory Commission, 1975). Note: car accidents caused at the time of the report about 50,000 deaths per year in the United states. These fatalities are not shown because data for large multiple-fatality accidents are not available*

The group was also critical of the Executive Summary which they felt did not give a good summary of the findings of the Main Report and was thus misleading.

The review is nevertheless sympathetic in principle to the attempt to quantify the frequency of events using fault tree and event tree methods and the consequences using hazard and injury models.

It states that it is incorrect to say that the use of fault trees and event trees is fundamentally flawed: it is just an implementation of logic.

On the other hand the practical application of the methodology involves various difficulties, including the availability of data, the statistical treatment of the data and the selection of appropriate models.

The group draws attention to the fact that the methodology is based on converting situations which are essentially continuous into discrete events and that this involves quite drastic simplification.

It is suggested that the problem of data is such that in some areas it is not appropriate to give absolute risk values but only bounding values.

The report criticizes the study for not always distinguishing clearly between different sources of values quoted: historical data, subjective judgements and models.

The review is sympathetic in principle to the use of values determined from expert judgement. Such judgements can be rather accurate as studies of betting demonstrate. It is necessary, however, to stay within the domain of experience of the expert and not require him to make estimates of events of which he has no experience.

The log–normal distribution is used to fit much of the data. The group are somewhat critical of some of the fits obtained, particularly for sparse data, but they accept the use of this distribution. With regard to the use of the median rather than the mean of this distribution, they state that this is more a matter of presentation than of substance and caused people to infer incorrectly that the study was predicting a lower failure rate than it actually did.

They are much more critical of the use made of the geometric mean, or square root bounding, and quote as an example the estimation of the probability p of failure of three adjacent BWR control rods. This probability is calculated as described above using Equation A23.6.1, where the values of the bound probabilities are the following functions of the failure probability p_{x} ($=10^{-4}$) of a single rod

$$p_{\mathrm{i}} = p_{\mathrm{x}}^3 = 10^{-12}$$

$$p_{\mathrm{u}} = 0.01p_{\mathrm{x}} = 10^{-6}$$

so that

$$p = 10^{-9}$$

An alternative model is the arithmetic mean which gives

$$p = 10^{-6}$$

There is thus a large difference.

The review devotes considerable attention to the problem of common mode failures. Such failures can cause individual equipment failures, can compromise redundant systems and can activate low probability accident sequences. The principal causes of such failure listed by the group are power supply failure, human error and external threats such as fire, explosion, earthquake and sabotage. They were unconvinced that the problem had been fully dealt with in the study and suggest that the best way to handle such events is to mount a defence against them at the start and so eliminate their effects.

It is suggested in the report that the treatment of earthquakes is inadequate. Attention is drawn to the work of Hsieh and Okrent (1976) showing that design and construction errors can greatly reduce the safety factors thought to be present in a design.

Another problem discussed at some length in the review is human factors and human error. The report expresses some disappointment that there were few comments on the human factors aspects of the study. Human factors affect the study in that human error can initiate an accident, can disable protective systems and can cause escalation, while on the other hand human action can mitigate an accident situation. The report recognizes that the human factors aspects of the study represent pioneering work and were well executed, but draws attention to the lack of data. The main thrust of the group's comments, however, is to the effect that the study probably gives too little credit for the effectiveness of human action in averting an accident.

The group identified various sources of uncertainty in the work, some biased towards conservatism and some to nonconservatism. Among the former factors were pervasive regulatory influence towards the use of certain parameter values and reluctance to claim full credit for effective human adaptability during accidents. Among the latter factors were questions of completeness and common-cause failure. They were therefore unable to determine whether the accident frequencies estimated were high or low, but were convinced that the error bounds had been greatly underestimated.

The report discusses the problem of the completeness of the identification of the hazards. The probability of core melt predicted in the study is two orders of magnitude less than the upper bound value which may be estimated from the number of melt-free reactor years accumulated. The report suggests that if there are unidentified accident sequences which can lead to core melt, some precursor events in these sequences should probably be occurring, although they may remain unrecognized. They suggest it is important to subject potentially significant sequences and precursors, as they occur, to the kind of analysis given in the study.

The report suggests that the results of the study cannot be applied directly to particular reactor sites. Application to a specific site would require more detailed study of the site characteristics such as topology and meteorology.

The report gives an account of the Brown's Ferry incident.

A23.19.2 Union of Concerned Scientists report

The review of the *RSS* by the UCS is more critical.

In the view of the UCS publicly available documents on the study suggest that it was not sufficiently independent of the nuclear industry, that its results were largely predetermined, that critical reviews were suppressed and that certain sensitive issues were avoided.

The report starts with a fundamental critique of the basic methodology. It reviews experience of fault tree analysis in the aerospace industry. It quotes as an example the use of the technique to estimate the reliability of the Apollo Service Propulsion System or SPS engine. One of the authors of the UCS report, W.M. Bryan, was in charge of reliability assessment during the testing of this engine. The estimated failure probability of the engine based on fault tree analysis was 10^{-4} while that estimated after testing was 4×10^{-3} so that the theoretical analysis gave an underestimate by a factor of 40.

The authors state that fault tree analysis for Apollo also failed to assure completeness of hazard identification. Many failures in the programme resulted from events which had not been identified as 'credible' and came as complete surprises. Some 20% of ground test failures and more than 35% of in-flight failures were not identified as credible prior to their occurrence.

The report states

> Fault trees, mathematical models and event trees were developed over 20 years ago and were [later] discarded . . . by NASA and . . . by the AEC as viable tools for estimating reliability/safety quantitative values.

It lists as techniques which are used probabilistic design analysis, propagation of error techniques, reliability estimation from small samples, malfunction simulation models and others.

The methodology used in the study is to synthesize accident sequences from failure data for single items. The UCS suggest that this approach fails to utilize information which is available on multiple failure accident sequences which have actually happened.

The review draws attention to the database used in the *RSS*, which was described above. The average age of the plants used in the study was 4 years. Two difficulties which arise from this are that often data collection was not well established and that failures due to ageing would scarcely have begun to appear.

The UCS criticize the assumption of random failure and suggest that failure rates may be significantly affected by ageing.

Attention is drawn to the danger of using historical failure data. The example is cited of the Skybolt rocket motor. A minor modification was made to the welding procedure for this motor. This resulted in flaws which were not revealed by quality assurance procedures but which caused the unit to explode under pressure and led to mission failures of the first two operationally launched vehicles.

An example is given where the study may have underestimated failure probabilities. For the High Pressure Coolant System (HPCS) the study uses a failure probability of 7.8×10^{-3} per demand. The report quotes data for four reactors in which there were 10 failures in 47 tests, a failure probability of 0.21.

Such instances also suggest that at some plants standards may be generally lower and the probability of an accident correspondingly higher, perhaps by an appreciable factor.

The report is critical of the use made in the study of the lognormal distribution to express the uncertainty in failure rate data. It suggests that it is not at all clear that this is the correct choice.

The report quotes the following comments by Yellin (1976):

The basic fault tree model therefore begins from estimates of the logarithms of the component failure probabilities, rather than from the probabilities themselves. In view of this use of the log–normal input distributions, one should also evaluate the accuracy of roughly 10–20% in their estimates of these output logarithms of failure probabilities, while it is suggested here that the evidence presented in *WASH-1400* is in fact consistent with uncertainties of order 50%. This difference of opinion is crucial, since for a typical failure probability of 10^{-6}, an accuracy of 10–20% results in an overall uncertainty factor of 10 in probability, while an accuracy of 50% results in an overall uncertainty factor of 1000.

The use of the median instead of the mean of the lognormal distribution is also criticized as incorrect. The former is some 2.5 times less than the latter. The authors believe that its use results in the study in underestimation of the risks by this factor.

The assumption of independence of events is criticized by the report, which devotes considerable space to the problem of common mode failures.

The report suggests that the *RSS* underestimates the importance of failures which occur in accident sequences as the result of previous failures and also of failures due to incorrect design.

The *RSS* found that common-cause failures do not make a significant contribution to the overall risk, but the UCS suggest that this contribution may have been underestimated. The example given is the miscalibration of four instruments in turn. The probability p of miscalibration of a single instrument is given in the study as 3×10^{-3}. For dependent failures of this kind the overall probability p of failure would be calculated using the study methodology as the geometric mean of the case for four independent failures and for tight coupling between failures. For the latter case, which gives the upper bound, the probability p_u is

$$p_u = 3 \times 10^{-3} \times 10^{-1} \times 1 \times 1 = 3 \times 10^{-4}$$

The last three terms are based on tight coupling. Then, the estimated probability p is

$$p = \left[(3 \times 10^{-3})^4 \times 3 \times 10^{-4}\right]^{1/2} \approx 2 \times 10^{-7}$$

Thus, the estimated ratio of the probability of the common-cause failure (2×10^{-7}) to the probability of the single failure (3×10^{-3}) is approximately 10^{-4}. The UCS compare this figure with their own estimate obtained by examining the common-cause failures in the *RSS* database. Out of 303 failures 33 are identified as common-cause. They take three of these failures as common-cause multiple miscalibration failures and thus obtain an estimate of 10^{-2} for the probability ratio referred to. This differs from the *RSS* estimate by a factor of 100.

The review gives the following breakdown of the 33 common-cause failures in the *RSS*

Failure	*No. of failures*
Drift of instruments, etc.	4
Miscalibration of instruments, etc.	5
Design error	6
Component failure	9
Environmental effects	6
Human error	2
Unknown	1
Total	33

The review refers to an incident on the Oak Ridge Research Reactor where the reactor had to be operated for 5 h without emergency cooling protection due to seven sequential common mode failures, each involving three parallel elements, making a total of 21 failures in all.

The review also considers what it calls common event failure which may lead to common mode failures. These events include fire, turbine missiles, earthquakes and sabotage. The UCS give an alternative analysis of the probability of core meltdown in the Brown's Ferry fire based on the relief valve failures and obtains a value of 0.03 instead of the *RSS* value of 0.003.

The review draws attention to the problem of design adequacy. The equipment may be reliable in the sense that it functions, but it may not be capable of fulfilling its task. For the Emergency Core Cooling System (ECCS) the *RSS* assigned a probability of failure on demand of less than 0.1. The UCS argue that ECCS systems have not been tested under accident conditions and may well lack the basic capability and thus have a higher failure probability.

Also, in the context of design adequacy the UCS take issue with the value used in the *RSS* for the failure frequency of the reactor pressure vessel. The *RSS* used a figure of 10^{-7} per year. The UCS argue that for non-nuclear pressure vessels the failure frequency is approximately 10^{-5} per year and that there is no justification for using a value 100 times less. They base their argument partly on the fact that the failure rates of components in nuclear plants are not greatly different from those in non-nuclear plants. They quote Professor Rasmussen

> Probably one of the most serious issues that the [nuclear power plant] intervenors can raise today, with good statistics to back their case, is that nuclear power plants have not performed with the degree of reliability we would expect from machines built with the care and attention to safety and reliability that we have so often claimed.

The UCS also refer to comments made by Sir Alan Cottrell, formerly Chief Scientific Adviser to the British Government, emphasizing the problem of dealing with deterioration of the vessel in a situation where, being radioactive, it is extremely difficult to replace. The UCS review includes an appendix by Cottrell on reactor pressure vessel integrity.

They also quote the following qualifications given in the *Marshall Report* with respect to such reactor pressure vessels:

> That it is essential to confine the operational transients to unusually narrow limits in order to avoid excessive crack growth by metal fatigue.

That emergency core cooling water should be injected at an unusually high temperature in order to minimize the risk of fracture by thermal shock.

The UCS list a number of safety issues which are addressed inadequately or not at all in the *RSS*. These include the hazards of loss of containment through electrical penetration seals, of earthquakes and of sabotage as well as the ageing problem already mentioned.

The UCS consider that the *RSS* dismisses too readily the risk from earthquakes. They give a number of quotations on the inability of seismologists to predict earthquakes. Thus, C.R. Allen (1967) states:

> Almost every large earthquake that has occurred in California has proved to be surprising in terms of what would have been expected by geologists, seismologists, and engineers at the time.

and Greensfelder (1971) states:

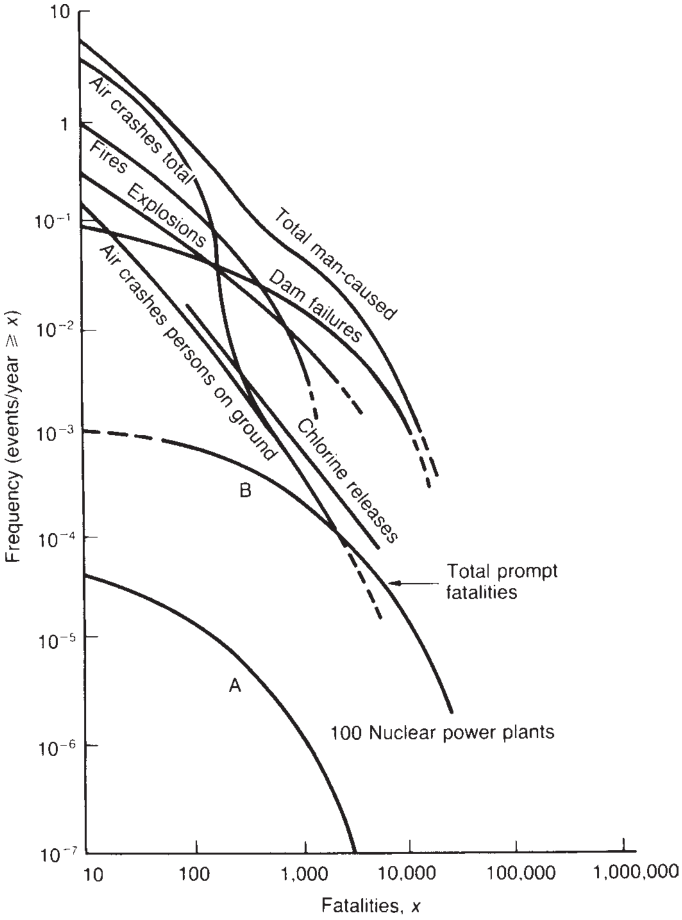
> Thus the San Fernando earthquake occurred in an area which has had relatively low seismicity and was not caused by movement on a major, historically active fault, such as the San Andreas or one of its branches. In fact, portions of the fault associated with this shock were not previously mapped . . .

The UCS argue that at the least the earthquake hazard introduces a much larger uncertainty than the *RSS* allows. The review includes an appendix on the earthquake hazards at the Diabolo Canyon nuclear reactor site.

On sabotage the UCS argue that it is indeed difficult to quantify but that it is a relevant factor in considering nuclear safety. They draw attention to the fact that the saboteur may be able to deliberately defeat many of the factors which normally operate to mitigate an accident.

The review makes a number of criticisms of the gas dispersion model, of the models of population exposure and of the relations for injury from radioactivity.

The UCS are doubtful about credit claimed for evacuation. Among their reasons are lack of emergency plans and failures in specific emergencies. They quote the failure to evacuate at Browns Ferry.



(a)

Figure A23.7 *Reactor Safety Study: Alternative FN curves for fatalities for 100 reactors proposed by the Union of Concerned Scientists (UCS, 1977): (a) early deaths and (b) total deaths. Curve A is that for early deaths given in the original study, curve B the proposed alternative*

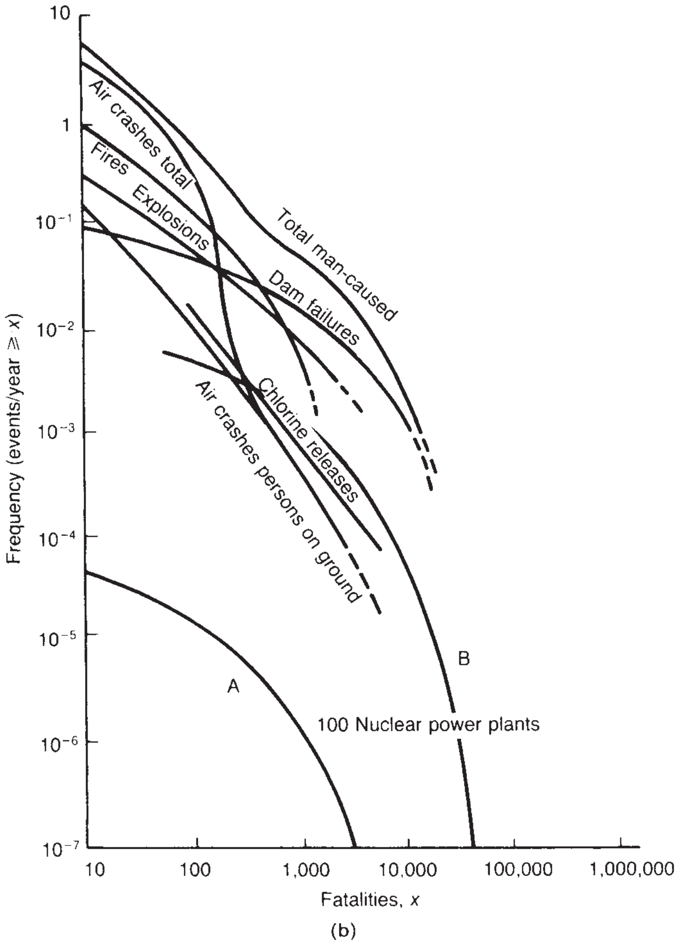


Figure A23.7 *continued*

A number of criticisms are made by the UCS of the handling of the results from the *RSS*. One criticism centres on the tendency to present the results simply as showing the risks of nuclear power to be very low and to play down the qualification and the uncertainties. Another is that the way the study was handled did not allow an effective process of peer review.

The large changes made between the draft and final reports also attract criticism. In some cases these changes exceeded the uncertainty bounds given in the draft report.

The Executive Summary is criticized as overoptimistic and misleading.

The UCS conclude that the *RSS* is not usable for policy decisions.

The review gives an alternative statement of the risks, the differences being partly of substance and partly of presentation. The UCS estimate of the frequency of a major release is 1 in 10,000 per reactor year, which is 20 times that of the *RSS*. The upper bound based on the number of incident-free reactor years was 1 in 300. The estimate of the consequences of such a release is that the early fatalities and injuries would be 10 times greater than in the *RSS*. In individual cases the consequences might be 100 or 1000 fold worse than the *RSS* predicts. The UCS estimate of the FN curve for early deaths is shown in Figure 23.7(a). The UCS also estimate that the late deaths are underestimated in the*RSS* by a factor of 2–5 and further argue that the FN curve should show the total deaths. Figure A23.7(b) shows the curve which they give for this.

ACMH Model Licence Conditions

Contents

The Second Report of the Advisory Committee on Major Hazards (Harvey, 1979b) presents in an appendix a set of model controls for a major hazard installation in the form of 'Model Conditions for a Possible Licensing Scheme for Selected High Hazard Notifiable Installations', although the report leaves open the question of whether the use of licensing or regulations is the best method of implementing such controls. The appendix is prefaced by the statement:

> 'The conditions outlined in this appendix have been written to give guidance as to the range and scope of the requirements that might be required if a licensing scheme of control were adopted for major hazard installations with the highest hazard potential. . . . The Committee is not yet in a position to say if certain installations should be regulated in this way until more information is available, particularly from the proposed Hazardous Installations (Notification and Survey) Regulations. It is, however, clear that there is a gradation of hazard with size and complexity of plant, and as this is increased there should be a greater degree of control and surveillance by the organisation in control of such activities. Thus this appendix has a wider application than the possible requirements for a licensing system of control. It is recommended that any organisation operating a major hazard plant, particularly one at the highest level of hazard potential, should review and satisfy itself that it could demonstrate that the requirements given below are adequately met.'

The full text, which is reproduced by courtesy of the Health and Safety Executive (HSE) and HM Stationery Office is given below.

A24.1 Model Conditions for a Possible Licensing Scheme for Selected High Hazard Notifiable Installations

With regard to a possible licensing system it is recognized that a licence is the most stringent form of control under the Major Hazards arrangements and would be applied only to those Notifiable Installations which present the greatest hazard potential. The licence would be granted to the organization which operates the installation and would be valid only for the specified location.

The approach adopted to licensing would be that foreshadowed by the Robens Committee and embodied in the Health and Safety at Work etc. Act 1974, namely that safety is the responsibility of the organization which should demonstrate that it is taking appropriate measures to ensure effective control of the hazards.

The licensing procedure might be in two stages. At the first stage, the organization would provide the HSE with a statement of intent covering the nature of the proposed installation, the hazards and the features of the design and operation intended to control the hazards. At the second stage, the organization would provide HSE with design and operating information to show how the statement of intent is implemented.

The documentation required might be in two parts corresponding to these two stages and consist of:

Part 1
(1) The Systems Documentation;
(2) The Preliminary Design Document.

Part 2
(1) The Background Documentation;
(2) The Design Document;
(3) The Operating Document.

The Systems Documentation, which is relevant to Licence Conditions 1–9, would be concerned with the general systems which the organization has set up to ensure safety and could be used in support of more than one licence application provided that it is up-to-date.

Details of the Preliminary Design Document are given in Licence Condition 10.

The purpose of the Preliminary Design Document would be to show the general nature of the installation and of any associated hazards. The onus would be on the organization to draw attention at this stage to any special features which might have an important bearing on the granting of a licence.

The Background Document would be documentation on the implementation of Licence Conditions 1–9, in relation to the particular installation.

Details of the main Design Document and the main Operating Document are given in Licence Condition 10.

The main Design Document would be essentially a more up-to-date and detailed version of the Preliminary Design Document, including additional details, such as materials of construction for the main plant items.

The main Operating Document, which incorporates the Operating Manual, would give details of the personnel structure for the operation of the installation.

A licence would be granted for a particular installation on a given site. The licence would not itself deal with questions of siting, but the issue of a licence is an indication that an installation meets certain standards and this is relevant to siting considerations.

The licensee would be required to inform HSE of significant changes which are proposed in any of the matters within the scope of the licence.

A24.1.1 Conditions for a licence

The conditions for the issue of a licence are that the licensee shall demonstrate to the HSE that the design, construction, operation, maintenance and modification of his installation are or will be to the standard appropriate to the installation and in particular that the following features of his organization are to such a standard:

(1) The management system;
(2) The safety system;
(3) The responsible persons;
(4) The arrangement for the identification of hazards;
(5) The arrangements for the assessment of hazards;
(6) The arrangements for the design and operation of pressure systems;
(7) The arrangements for the minimization of exposure of personnel;
(8) The arrangements for the administration of emergencies;
(9) The arrangements for reporting of and learning from incidents;
(10) The design and operating documentation.

A24.1.1.1 Licence Condition: The management system

The organization should show that it has and supports a management system and staff structure which combine to ensure continuing effective control of the installation and its hazards.

The staff concerned include contractors and consultants. This aspect is considered further in Licence Condition 3.

The organization should show the management structure, making clear the distinction between executive and advisory functions, and should give a brief job description for each post.

The management system should give full support to the personnel who are responsible for the design and operation of the installation. Important elements include a suitable and well understood management structure; adequate human resources including coverage of absences, vacancies and emergency situations; recruitment, training and career planning; and effective communications.

The management system should in particular provide satisfactory arrangements in the areas which are the subject of Licence Conditions 2–9. There should be comprehensive, formal and documented set of systems and procedures.

The management should define the objectives of its system of documentation in respect of immediate a communication and of record-keeping and should specify the extent of the documentation required and the procedures for producing it.

The management system should provide for thorough initial and continuing training of personnel in their work generally and in safety in particular.

Full use should be made of appropriate standards and codes of practice. Where there are standards or codes which have statutory backing or which are commonly recognized within the United Kingdom as constituting sound practice, these should be applied as a minimum. Where there are no approved or accepted standards or codes the situation should be covered by the adoption of sound practice and the use of in-house codes.

The management system should include formal procedures for the control of modifications made to the plant or to the process, whether during design or during operation.

The management system should require the independent assessment of features which are critical to the safe operation of the installation. This independent check is essential for inspection of pressure systems and for reliability assessment of instrument trip systems. The guiding principle is that the feature is critical to safe operation of the installation. It is acceptable that the check be done by an in-house authority provided that this is genuinely independent of the interested party. Thus pressure system inspection, for example, must be done by an authority independent of the operating authority, as described by Licence Condition 6.

The management system should contain a variety of arrangements for the periodic audit both of the continuing appropriateness of systems and of the continuing effectiveness of their implementation.

Background It is considered that in the case of major hazard installations the control of the plant and its hazards requires a considerable degree of formalization of communications through written systems and procedures, standards and codes of practice. This is essentially to encourage, and where appropriate enforce, collective and personal discipline by the use of operating methods which have been carefully thought out and which contain an appropriate level of checks and counterchecks to obviate problems and reduce errors.

It is recognized that there is always the problem of over-administration through paperwork and what at times seems like 'going through the motions' without apparently contributing anything useful. However, it is considered that a careful review of incidents will, time and again, illustrate that there was a loss in discipline because appropriate procedures either did not exist or were not observed.

There should be an interlocking set of systems and procedures to ensure safety through sound engineering and management practices. There is no upper limit to the number of procedures which can be formalized, but there is nothing to be gained by deliberately trying to maximize the number. The optimum number is that which leaves no obvious gaps but avoids creating confusion by overlapping.

Many of the required procedures are implicit in the various Licence Conditions which follow. It is evident that key procedures include those for the identification of hazards, the assessment of hazards, the control of maintenance through permits-to-work, the control of modifications to process or plant, the inspection of equipment, the operation of the process (normal and emergency), the control of access, the conduct of safety audits and the reporting of incidents.

Self-auditing features should be built into the management system in the form of formal instructions for periodic checks on those parts of the system which may become degraded or unnoticed. The operation of a permit-to-work system, for example, should be subjected to regular audit by some means such as an instruction, not merely an exhortation, to the plant manager to sample a proportion of permits each week.

A24.1.1.2 Licence Condition: The safety system

The organization should show that within the management system there is a safety system which is appropriate to the level of hazard inherent in the installation.

The safety system should in particular provide for satisfactory arrangements in the areas of the safety organization, safety objectives and assessment, safety consultative committees, and safety training.

The organization should show that it has people competent to operate the safety system.

Background Most of the aspects of the safety system mentioned are already legal requirements, but it is the object of this section to review their adequacy in relation to the major hazard installation.

A distinction can be drawn between the technological and human sides of safety. On a major hazard plant the technological features are obviously particularly important. The responsibility for these aspects rests primarily with the qualified technical staff in the design and operations areas. There should be no neglect, however, of the human side. On the contrary, on a major hazard plant it is more important than ever to run a 'tight ship' as far as safety is concerned.

The authority of the safety staff should be made clear, particularly in relation to the more technical aspects of the installation. Attention should be paid to the means of ensuring that the safety officers/advisers are effective and are seen to be so.

The safety objectives set for management and the assessment of the performance in meeting these objectives should be indicated. This may not be a simple matter of accident statistics. For major hazard installations there is an additional problem of avoiding rare but catastrophic events. This makes it important to monitor both the occurrence of 'near misses' and the degree of adherence to procedures and rules.

The programme of safety training provided for employees at all levels should be outlined.

Attention is also drawn to Licence Condition 9 which is concerned with the system of reporting of and learning from incidents.

A24.1.3 Licence Condition: The Responsible Persons

The organization should nominate Responsible Persons who are in charge of the design and operation of the installation.

The term 'Responsible Person' has a specific meaning in the context and is explained below.

The organization should show the management structure down to the lowest level of executive technical management, making clear the distinction between executive and advisory functions. There should be a job description for each post; the job descriptions for the posts held by Responsible Persons are particularly important.

The level of seniority held by the Responsible Person should normally be either the lowest or second lowest level of technical executive management.

It is envisaged that persons immediately senior to the Responsible Persons will themselves normally have been or be qualified to be a Responsible Person on major hazard installations, though not necessarily on those processes of which they are now in charge.

The organization should show that a person nominated as a Responsible Person is qualified to hold the post by reasons of his academic qualifications, practical training and recent relevant experience.

On the operations side, this experience should be experience in the operation of the actual process or of a similar process. Experience limited to design of the process or of similar processes and/or to operation of dissimilar processes is not acceptable. On the design side, the experience should be in the design of similar processes.

Where the process incorporates features of considerable technical novelty as a result of which no person has first-hand experience of operation of relevant full-scale plant even greater regard must be paid to the level of competence of the individual and normally experience of pilot plant operation would be required.

Where the installation is to be designed in part or in whole by an outside contractor it is the responsibility of the organization which will operate the installation to satisfy itself and to demonstrate to HSE that the design is to an appropriate standard. The minimum requirement is that there be a nominated Responsible Person in the operating company who has the duty of liaison with the contractor. Where practical it is also desirable to have nominated Responsible Persons in charge of design in the contracting company.

For convenience, reference is made here only to design and operation. The organization should enumerate all the project activities such as fabrication, construction, inspection, commissioning and satisfy itself and HSE that there are nominated Responsible Persons responsible for these activities.

It is emphasized that the ultimate responsibility for the safety of the installation lies with the organization which operates it.

Background The concepts of 'Responsible' and 'Authorized' Persons occur in various management systems. Our usage of these words is that 'Responsible' relates to a job, for example, plant manager, and 'Authorized' to a task, for example, signing a permit-to-work.

We have considered various models for Responsible Persons. These include those in the Mines and Quarries Act, the Merchant Shipping Act, the Factories Act (radioactive substances), the Explosives Act, the Medicines Act.

We have also considered the arrangement whereby the Department of the Environment advised by the Institution of Civil Engineers recommends individuals for the design of reservoirs.

Competence to do a job must depend on the definition of the job and its relation to other jobs. We began, therefore, with a consideration of management structures and reviewed possible general models for a large and a small firm. It became apparent, however, that this was not a particularly helpful approach and it was not pursued. However, in a concrete situation we do consider the presentation of such a management structure and job descriptions desirable.

With regard to the level of seniority we started with the proposition that the Responsible Person should be at the lowest level of the executive technical management. However, this could give rise to problems in some areas. For example, it is necessary to train for succession and by definition trainees must be at a lower level. Such additional lower levels are not normal in existing practice, would be wasteful and would not offer job satisfaction. We therefore prefer to leave a degree of flexibility. But we do attach importance to ensure that the responsibility is real rather than nominal and is at the lowest practical level.

Thus we envisage that the Responsible Person on the operations side would usually be capable of 'stepping down' and carrying out the job at the next level down.

With regard to selection of Responsible Persons we consider academic qualifications, practical training and recent relevant experience essential.

We think it is desirable that the person chosen should have the sort of broad scientific and technological education which a first degree in science or engineering usually gives. We consider that such a degree should normally be a necessary qualification. Exceptionally, however, people without a degree may be considered. We also attach importance to the ability of the person to recognize problems outside his sphere of competence and to his willingness to seek the advice of other experts.

We consider that although the Flixborough disaster has emphasized the importance of the integrity of the plant, there may be other major hazards where the integrity of the process is of at least equal importance. Thus, whilst it is probable that the Responsible Person will normally be an engineer there will be cases where he will be a scientist, for example, a chemist.

We attach particular importance to the selection of Responsible Persons on the operations side.

We lay particular emphasis on recent relevant experience. There is obviously room for discussion as to the 'relevance' of experience or the 'similarity' of processes. It is up to the organization to convince HSE on these points.

We stress, however, that we would not want this emphasis on recent relevant experience in any way to inhibit technological innovation or normal career development.

We accept that technological progress requires specialization. The professional institutions already recognize this and are considering a register of persons considered competent to design and operate major hazard installations. We are maintaining contact, although, whilst welcoming their interest, we see a number of difficulties in this approach.

The requirement to nominate Responsible Persons should not be seen as detracting in any way from the necessity for a team effort by management to achieve high standards of safety in plants which have major hazards.

A24.1.1.4 Licence Condition: The arrangements for the identification of hazards

The organization should show that it uses appropriate methods of hazard identification at all stages of the project.

The terms 'hazard identification' and 'safety audit' refer to mainly qualitative techniques which review the existence of a hazard.

The application of the techniques should be matched to the stages of the project, starting with coarse scale investigations and progressing to fine scale studies to discover detailed faults.

The management system should contain a formal requirement for the use of such methods, should specify the documentation required arising from this use and should monitor this use.

The organization should show that it has people competent to implement these methods of hazard identification.

Background The first objective of hazard identification is to reveal the substances or processes which have a hazard potential. The second objective is to identify all conceivable threats to the installation or its processes which might lead to loss of containment.

As technology has progressed identifying hazards has become in some ways more difficult. In particular, there are many hazards which are not revealed by traditional visual inspection. It has become necessary, therefore, to develop additional methods of hazard identification.

An illustrative list of methods is given in Table A24.1

Since every human enterprise involves the possibility of error it follows that the soundness of the management of the potentially hazardous installation is the predominating factor and that the first essential in all cases is an audit of the management system as a whole.

It is recognized that there is a wide variety of methods of hazard identification in use in industry and that different techniques are applicable to different situations. There is no intention of imposing any particular method.

It is necessary that the use of these methods be a requirement of the management system, which also should specify the degree of recording and documentation required and should contain a mechanism for auditing the application of the techniques to ensure that they are used.

The people who have to implement these techniques must be competent to do so. HSE should be able to advise on opportunities for training in this area.

Hazard identification covers much the same ground as safety audits in the broadest sense. The Chemical Industries Association has published two guides entitled *Safety Audits: A Guide for the Chemical Industry* (1973) and *A Guide to Hazard and Operability Studies* (1977).

Table A24.1 *Some methods of hazard identification*

Project stage	*Hazard identification method*
–	Management and safety system audits
All stages	Checklists Feedback for workforce
Research and development	Screening and testing for Chemicals (toxicity, instability, explosibility) Reactions (explosibility) Impurities Pilot plant
Predesign	Hazard indices Insurance assessments Hazard studies (coarse scale)
Design	Process design checks Unit processes Unit operations Plant equipment Hazard and operability studies (fine scale) Failure modes and effects analysis Fault tree and event trees Hazard analysis Realibility assessments Operator task analysis and operating instructions
Commissioning	Checks against design, inspection, examination, testing Non-destructive testing, condition monitoring Plant safety audits Emergency planning
Operation	Inspection testing Non-destructive testing, condition monitoring Plant safety audits

A24.1.1.5 Licence Condition: The arrangements for the assessment of hazards

The organization should show that the hazards identified by the means described in the preceding section have been removed or that the associated risks have been reduced to a minimal level.

In this context 'minimal' means the probability that an employee or member of the public will be killed or injured or that property will be damaged is at least as low as in good modern industrial practice.

The method of demonstrating that the risks are at a minimal level should be comprehensive and logical.

The method may consist of:

(1) the use of codes of practice generally recognized in the industry;
(2) the use of special testing;
(3) the use of calculations based on appropriate data.

In many cases it will be sufficient to show for all or at least some aspects of the hazard that a generally recognized and accepted code of practice is applicable and has been followed.

Where there is any aspect of the hazard, the risk of which cannot be reduced to a minimal level by following a recognized code of practice or by special testing, then, whenever meaningful quantitative methods should be used to demonstrate that the risk has been reduced to a minimal level. These quantitative methods will normally consist of three steps:

(1) An estimate of the consequence to employees and the public.
(2) An estimate of the frequencies with which hazardous situations will occur.

(3) Comparison of (1) and (2) with the other risks to which people are normally exposed in order to show that the risk under consideration is relatively small.

The management system should contain a formal requirement that such methods of hazard assessment should be applied.

The organization should show that it has access to people competent to implement these methods.

Background Having identified hazards, as described in the previous sections, it is necessary to know that the associated risks have been reduced to a minimal level.

It is envisaged that the method of demonstrating that the risks are at a minimal level will normally be based on a fault tree approach, but that a detailed development of all parts of the tree will not generally be required.

Sometimes it is possible to remove a hazard completely, for example, by replacing a flammable or toxic raw material by a non-flammable or non-toxic one.

More often, the hazard cannot be eliminated completely, though the risk can be reduced to any desired level by the use of protective equipment. For example, the risk that a particular vessel will burst because of overpressure can be reduced by fitting a relief valve suitable for the duty, adequately sized and properly maintained. This does not eliminate the hazard completely as there is a small probability that the relief valve will fail to lift when required. Even if two relief valves are fitted, there is still a very small probability of coincident failure.

In many cases, codes of practice provide generally recognized and accepted methods of reducing a hazard to a minimum level. For example, in the case just considered, it would normally be sufficient to show that the vessel is fitted with a relief valve, adequately sized and properly maintained, as relief valves have been generally recognized for many years as an accepted way of reducing to a minimal level the probability that a vessel will burst.

Similarly, if fracture of pipework has been identified as a hazard, it would be sufficient to show that the pipework has been designed and constructed and will be operated and maintained in accordance with a recognized and relevant code of practice.

Codes of practice should not be used outside their area of applicability. Codes of practice for pipework, for example, do not cover fracture by projectiles and if it is necessary to take the latter into account, a separate study is necessary.

Moreover, codes of practice imply acceptance of some level of probability of the hazard materializing. This level will be unacceptably high in relation to some major hazards.

In some cases, it may be necessary to carry out special tests to quantify aspects of particular hazards.

Where there is no generally accepted code of practice and where the problem cannot be resolved by testing, but where it is reasonably practicable to show quantitatively that the risk has been reduced to a minimal level, this should be done. In some cases, this cannot be done because of lack of data or of a suitable model to describe the system. In these cases, judgement will have to be used.

Examples of hazards which may not be covered by recognized codes of practice and which, if they produce major effects, would have to be individually assessed, are:

(1) runaway reactions (e.g. decomposition and polymerization reactions);
(2) impact of moving objects (e.g. cranes, vehicles, missiles from explosions);
(3) failure of instrumental protective systems;
(4) failure of services (e.g. electricity, water, compressed air).

These can be described as events leading to possible loss of containment.

The hazard quantification will normally consist of three stages in which probability and consequence must both be considered; sometimes it will be necessary to consider a number of possible outcomes differing in probability and consequence. An event which has the potential to kill many people may not cause great concern if the probability of it occurring is sufficiently small. We do not prohibit football matches because there is a small chance that an aeroplane may crash on the crowd. On the other hand, we would not build a new football ground at the end of a busy runway.

(1) The first stage is the estimation of the probable consequence of the hazard. This may be based on past experience or it may be estimated from a theoretical study of the problem. The consequences may be expressed as the probability that an employee or a member of the public will be killed or injured or as the probability that extensive damage will be caused to the property of others or both.
(2) The second stage is the estimation of the probability that the hazard will occur. Again this estimate may be based on past experience, or it may be synthesized from data on the failure rates of individual components or pieces of equipment.

In estimating the probability that the hazard will occur it is necessary to assume that certain standards are followed in the operation of the equipment, for example, that relief valves are tested regularly. If these standards are not followed the conclusions of the hazard quantification are no longer valid.

(3) The third stage is comparison of (1) and (2) with the other hazards to which people are exposed in order to ensure that the risk under consideration is minimal.

This implies the use of a criterion against which risks can be judged. It is not intended that any single criterion should cover all cases.

If it is not possible to carry out a complete study as indicated (i.e. stages 1–3), it may be possible to carry out a partial study and, if so, this should be done, as it helps to identify those aspects of the problem which have most effect on the probability and consequences.

Where a new feature is used in place of one of proven reliability then it should be shown that the new feature is at least as safe as, and preferably safer than, the original. For example, if an instrumented protective system is used in place of a relief valve it should be shown to fail no more often, and preferably less often, than a relief valve.

In other cases it may be appropriate to show that the risk to an employee is no greater than that for employees in the industry as a whole or to show that the risk to a member of the public is comparable with the other risks to which the public are exposed without their consent.

It may be noted that it is difficult to find examples of instances in which members of the public have been killed as a result of accidents on major hazard installations. In most cases, if the risk to employees is minimal the risk to the public will also be minimal; although a lower level of risk is required, the public are usually further away.

It is necessary that the use of quantitative methods, whenever meaningful, should be a requirement of the management system. This should specify the recording and documentation required.

In some cases a detailed study may be required taking many days or even weeks, but in other cases relatively simple calculations may be sufficient.

The organization should show that it has access to, and uses as necessary, people competent to assess hazards, but these people need not be in its full-time employment; they may be consultants.

Quantitative methods provide a means to assist management to choose those measures which are 'reasonably practicable' for providing a safe plant and system of work.

A24.1.1.6 Licence Condition: The arrangements for the design and operation of pressure systems

The organization should show that it has a formal and well-understood management system for controlling and monitoring the design, fabrication, commissioning, operation, inspection and testing of pipework, vessels and other equipment together forming the constituents of a pressure system which may give rise to a serious hazard.

The term 'pressure system' refers to a linked series of equipment items operating at a pressure either above atmospheric or under vacuum, together with all the interconnecting pipework. Such systems commonly form processing units, but the definition includes also storage and handling installations.

The management system of control should be in two parts, and should be effected through two recognized channels of authorization, related to Design and to Operation.

The management design authority should identify and state the design parameters within which the pressure system is to operate and the conditions for which each component part of the pressure system shall be designed. It should also define the code under which the individual components shall be designed, or where no design code exists should cause sufficient work to be undertaken to satisfy themselves, either by experiment or by the use of specialist advisers, that the design is at least as safe under all foreseeable circumstances as the standard demanded by recognized codes.

The design authority should also define the standards to be used for the pressure system during the fabrication and construction stages. Whenever possible the standards specified should be those quoted in recognized codes applicable to the particular pressure system.

Management should ensure that an appropriate inspection system is operated during fabrication and construction work to check that the standards set by the management design authority are being met. This inspection system may be in the same management organization as the design authority, or it may be appropriate to use one of the engineering insurance companies or other approved inspection agency. The inspection system should not be part of the operating authority. The design authority should also specify the written evidence required to demonstrate that the plant has been fabricated, constructed and proof-tested, in accordance with the design requirements. Copies of documentation forming this written evidence should be verified, preferably by the inspection agency before the pressure system enters service. Copies of all documentation relating to the design parameters, and to the verification by the inspection system, should be retained by the design authority and should also be available on the works on which the pressure system is operated.

The operating authority should prepare a comprehensive set of instructions based on information issued by the design authority and upon an analysis of hazards involved. These instructions should set out clearly the way in which the pressure system shall be operated in both normal and abnormal circumstances, and the way in which the pressure system is to be protected from the effect of conditions more extreme than those permitted by the design authority. These instructions, which should be readily available to all those responsible for operation, inspection and repair of the pressure system, should set the limits within which the system is to be operated. Any variation in these limits outwith the parameters set by the design authority should be referred to the design authority or other independent qualified body for approval before fresh instructions are issued. Such submission and approval should be made in writing and copies retained in the works for future reference.

The operating authority is responsible for ensuring that any repairs and modifications are designed, fabricated and tested to a standard not less than that used by the design authority for the original system. The operating authority should have a system of documentation which controls the repair and modification procedures, so that modification to the pressure system cannot be made without written authority from an authorized person.

Thus, instructions prepared by the operating authority should include formal procedures for identifying and making process modifications, for identifying and making plant modifications and for restarting the plant after discovery of a serious defect.

The operating authority should also provide and enforce the use of a code which ensures the continuing safety of the pressure system by a regular inspection of the equipment and the safety devices which are provided to protect that equipment. Such an inspection code should meet the following criteria. First, that a register is held on each works in which each item of equipment is given a unique designation and an engineering description which adequately describes the design and fabrication details and also details of operating conditions, both normal and maximum. Secondly, that the code should specify the frequency of inspection for the various classes of equipment and should also specify rules concerning the selection and training of inspectors. There should also be rules by which inspection frequencies may be increased or reduced, decisions being based upon the result of inspection records which should be held in the register. The code should specify rules which guarantee the independence of the inspecting system from the operating authority, either by appointing external inspection authorities, or by making satisfactory arrangements for the in-house inspection authority to be responsible to a senior member of the organization who has the design authority within his charge.

The organization should show that it has people competent to execute the control and monitoring functions described above in both the design authority and operating authority areas. It should also show that the inspection service is truly independent of the operating authority.

Background The control of design and operation of pressure systems is a cardinal feature for ensuring safe operation of major hazard plants.

The separation of management control into the areas of a design authority and an operating authority has been made in order to bring out clearly the separate responsibilities of these two parts of the total organization which designs, builds and operates a major hazard plant. The areas of authority interlock, and in small organizations there may be sharing of some specialist personnel. It is important, however, that the design concept and subsequent modifications to that concept should be controlled by an authority separate from the operating authority. In cases of contractor design, the organization will have to show that the contractor can carry out the duties of a design authority, particularly in the matter of documentation concerning the design parameters for the pressure system and the fabrication details, and in the provision of competent people for authorization.

The use of a regular inspection is an essential feature of the safe continued operation of a pressure system. The register of equipment and inspection reports is the linchpin around which this inspection system is built. Decisions on the frequency of inspection and the nature of satisfactory inspection procedures should be taken by the inspecting authority with advice from the design authority. An essential feature of the integrity of the system is that the inspectors and their management are not under the technical control of the operating authority. In small organizations, considerable use can be made of external inspection agencies and other specialist help. In large organizations, such facilities are likely to be provided in-house. In those cases the organization should take particular care to show the independence of the inspection agency.

It is important that safety devices such as relief valves, non-return valves and vents are included in the register of pressure systems and are subject to the same type of inspection and testing arrangements as are specified for the pressure equipment. Details of testing and frequency of examination may well be different from arrangements made for pressure equipment, but the principle of inclusion in a register, together with test and inspection notes, is essential.

A system for registering and inspecting pressure vessels and other equipment and for the keeping of verification documentation which satisfies many of these criteria is described in BS 5500: 1976 Unfired fusion welded pressure vessels, in the Pressure Vessel Inspection Code and in the draft Piping Systems Inspection Code of the Institute of Petroleum.

A24.1.1.7 Licence Condition: The arrangement for minimization of exposure of personnel

The organization should show that it has assessed the hazards to personnel involved in the installation and that where necessary it has taken steps to reduce these hazards to a minimal level. In particular, measures should be taken to limit the number of people at any one time in areas of high hazard to a minimum consistent with safe and efficient operation and to afford protection to exposed personnel, who may include operating personnel, maintenance personnel, investigation teams, construction workers and visitors.

Background This matter is fully dealt with in chapter 7 of this report.

A24.1.1.8 Licence Condition: The arrangements for the administration of emergencies

The organization should show that it has assessed the hazards involved in the installation in relation to major emergencies and has maintained emergency plans.

Emergency planning should include identification and assessment of possible major emergencies; nomination of persons responsible for administering an emergency; development of procedures for declaring, communicating and controlling the emergency and for evacuation; provision of buildings such as a control centre or refuge rooms and of equipment such as an alarm system; designation of works emergency teams and definition of duties of other workers; liaison with external services including police, fire and medical services; training and exercises for emergencies.

Background A guide *Recommended Procedures for Handling Major Emergencies* is published by the Chemical Industries Association (second edition, 1976). This covers primarily the administration of emergencies within the works.

The guide also deals briefly with the planning of action, such as evacuation, which may be required outside the works. This is particularly important for certain major hazards. It should be emphasized in this connection that for toxic gas hazards the value of the time bought by any distance separating the factory and the public may be wasted if there is no evacuation plan.

A24.1.1.9 Licence Condition: The arrangements for reporting of and learning from incidents

The organization should show that it has prepared a schedule of signals to be recorded and that the relevant instruments are housed in such a way that an accident on the plant is unlikely to prevent recovery of the records.

The organization should show that it has a system for the reporting of incidents which might endanger the installation or lead to loss of containment and that it uses the information obtained from this reporting system to learn how to reduce these hazards.

These requirements for the reporting of hazardous incidents are additional to the existing statutory requirements. They have two main objectives. One is to ensure the reporting within the company of the ‘near miss’ type of incidents which often precede an accident. The other is to obtain data at national level on incidents related to serious hazards. HSE may request that certain types of incident be included.

Background There already exist certain statutory requirements for the reporting of incidents. These include:

(1) The Petroleum (Consolidation) Act 1928;
(2) The Factories Act 1961;
(3) The Dangerous Occurrences (Notification) Regulations 1947;

as well as those specific to explosives factories, mines and quarries, and nuclear installations.

These requirements are mainly concerned with accidents causing plant downtime, lost-time accidents and fatalities.

It is well-known, however, that for every serious accident there are numerous incidents, including ‘near misses’. Since they are more numerous, these incidents offer greater scope for learning and improvement.

It is therefore proposed that the organization should have its own reporting system covering the type of incident significant in relation to its particular hazards.

We have deliberately not specified the incidents which should be reported but we have in mind incidents relating to such matters as:

(1) incidents involving serious operator error;
(2) incidents involving trip system malfunction or disarming;
(3) malfunctions of valves, for example, pressure relief, non-return;
(4) leaks of flammable materials;
(5) leaks of toxic materials;
(6) leaks and fires at pumps;
(7) fires and explosions in furnaces;
(8) storage tank collapse.

The important point is that the reporting system should be tailored to the needs of the organization.

There may also be certain types of incident on which HSE wish to collect information nationally. In this case it may request their inclusion in the reporting scheme. Again we have not specified these incidents but an obvious one is the unconfined vapour cloud explosion.

These reporting requirements should be seen in relation to the fact that we have not recommended that all major hazard installations have a ‘black box’ recording instrument system. We consider that the arrangements proposed here are a more efficient way of learning both at company and national level.

The reporting system is intended primarily to assist the organization to learn from incidents and it should show that it has formal arrangements to do this.

A24.1.1.10 Licence Condition: the design and operating documentation

The organization should provide full documentation on the design and operation of the installation. The documentation required is as follows:

Part 1 Documentation
(For Part 1(a) The System Documentation see Introductory Section of this appendix.)

Part 2(b) Preliminary Design Document This should contain:

(1) A brief description of the process and should include the nature of any chemical reaction involved and the various operations to which the material in process is subjected. In addition, any other exothermic reactions which may arise if operating conditions fall outside the design values, should be specified.
(2) A comprehensive description of the nature of the hazards in the materials handled (toxic, flammable, explosive materials), of the objectives to be achieved in order to limit these hazards and of the methods in plant design and operation necessary to achieve these objectives.
(3) A statement of any less hazardous process which could have been used and the reasons for selecting the particular process in question. This might include outstanding economic advantages, factors relating to the availability of raw materials, the avoidance of particularly difficult engineering operations or the necessity of making a product of a particular purity.
(4) A process flow sheet, indicating quantities, the temperatures and pressures of materials at each stage and the vessel inventories, and the flow-rates in each of the principal flowlines. The reasons why such pressures and temperatures must be used should be given. Mass and heat balance diagrams should be given where appropriate.
(5) A list of the main plant items, specifying the capacity, design pressure, temperature limits for safe operation (upper and lower), and any special features of construction, together with the actual operating conditions. Details of services should be given.
(6) Details of the principal standards and codes to be used in the design.
(7) A statement of the inventory of all hazardous materials in process and of the steps taken to keep this at the lowest level consistent with safe and efficient operation.
(8) A statement of the method whereby the process will be controlled. Abnormal features, with particular reference to hazards, should be highlighted and references made to any special features, including trip systems.
(9) A list of all hazardous materials in bulk storage which may be endangered by a process incident and the steps to be taken to minimize the risk of their involvement.
(10) A statement of all materials and services needed to maintain safe operation of the plant and of the steps taken to ensure their continuous availability.
(11) A statement of any noxious effluents and their methods of treatment.
(12) A site layout showing the proposed plant and control room, and their position relative to other installations and buildings in the works, to loading bays at tanker terminals, to plants in neighbouring works and to the public area.
(13) A statement of the location and construction of the control room.
(14) The routing for all vehicles needing access to the plant, whether for the supply of materials and removal of products, or for maintenance or emergency purposes.
(15) An account of the procedures for maintaining effective liaison between the company and any outside organizations involved in the design or construction of the plant.
(16) Details of actual experience of the company, or of availability of experience from external sources, in operation of pilot and production scale plants, for the same or a similar process.
(17) Manning levels on the plant.
(18) Proposals for dealing with emergency situations.

Part 2 Documentation
(For Part 2(a) The Background Documentation see Introductory Section of this appendix.)

Part 2(b) The Design Document This should contain:

(1) An updated and detailed statement of all materials submitted in the Preliminary Design Document, including the process flowsheet, quantities and flowrates of all materials in process and storage areas, heat and material balances, instrument diagrams and plant layout diagrams.

(2) Details of all principal plant items, as in item 5 of Part 1(b), giving codes used, materials of construction and any special features.
(3) Installation drawings and pipe layouts.
(4) Documentation on hazard assessments and reliability studies.

Part 2(c) The Operating Document This should contain:

(1) A statement of the technical staff structure, including names of the Responsible Persons, together with details of standby arrangements for absence such as sickness or holidays, and of call-in arrangements.
(2) A statement of the numbers of operating personnel and of their training with particular reference to emergency procedures.
(3) The Operating Manual. This should include details of the start-up, normal shut-down and emergency shut-down procedures.

Appendix 25

HSE Guidelines on Developments near Major Hazards

Contents

The Third Report of the Advisory Committee on Major Hazards (Harvey, 1984) contains an appendix on 'The Siting of Developments in the Vicinities of Major Hazards: HSE's Draft Guidelines to Planning Authorities. The full text, which is reproduced by courtesy of the HM Stationery Office, is given below.

A25.1 The Siting of Developments in the Vicinities of Major Hazards: HSE's Draft Guidelines to Planning Authorities (by the Health and Safety Executive – Major Hazards Assessment Unit)

A25.1.1 Introduction

The control of risks from major hazards may be achieved in various ways, for example:

(1) limit the amount of hazardous material present;
(2) reduce the likelihood of an accidental release of material;
(3) plan for emergencies;
(4) reduce the number of people exposed to risk.

Some of these measures may be taken within the installation, particularly at the project planning stage.

In many cases the situation in the installations is already fixed and the scope for improvement under the HSW Act is fully utilized. Even so, there may remain some residual risk. It is unlikely that the residual risk could justify the removal of existing populations by the termination of viable land uses. However, it is possible to inhibit an increase in the population at risk by control of new developments under planning legislation.

It is the purpose of HSE's advice to facilitate planning control where appropriate. Planning authorities are expected to include the factor of risk in their consideration of a planning decision. Thus, the types of development near major hazards should be deliberately chosen to minimize the population at risk.

HSE takes as a starting point the assumption that the major hazard installation complies with the requirements of HSW Act. It is then necessary to assess the level of residual risk to a proposed development in the vicinity, and to judge whether this might be a significant factor in the planning decision. HSE's assessment takes account of the consequences and likelihoods of various accident scenarios, and the implications of variations in vulnerability between different types of development. In some cases, the assumption of compliance with HSW Act implies a precise standard.

In other cases the standards are not precisely defined, or it may be possible to comply in a variety of ways. The individual characteristics of installations are taken into account where possible, but there are limits to the amount of detail which can be considered. It may be necessary to assume average performance in the absence of obvious individual variations, or for cases which are being assessed on paper.

This note deals only with the provision of advice on proposals for new developments in the vicinity of existing major hazard. The assessment techniques are used in a similar way when considering the siting of new major hazards in relation to existing buildings, but the judgement of the significance of the risks may be different. For example, the siting of a new major hazard may be constrained by the need to integrate it with existing plant. The application of a simple 'reciprocal rule' for the siting of new major hazards would neglect the differences in availability of sites for the two situations. There is also the possibility of seeking special safety standards on a new plant to facilitate its siting.

A25.1.2 Assessment: likelihood and consequences of an accident

The first part of the assessment is objective in the sense that it does not include social or political judgements, but it does include estimates of various factors where data is more or less unavailable. Thus it includes technical judgement by professional risk assessors. There is inevitably some uncertainty introduced by this judgement process and by lack of precision in basic data. This does not prevent the derivation of reasonable conclusions but it does imply that some caution is necessary. The technical judgements may tend to lead to an over-estimate of the risk level. If a planning decision is finely balanced, a more detailed review of assumptions may be worthwhile.

Assessments of risk from different materials differ in detail but they have many features in common. The basic sequence of events for LPG and chlorine are:

(1) LPG:
    plant failure;
    release;
    vaporization;
    mixture with air;
    ignition;
    explosion and/or fire;
    blast and/or heat propagation;
    impact (either directly on people, or on buildings which collapse or burn).
(2) Chlorine:
    plant failure;
    release;
    vaporization;
    mixture with air;
    travel downwind;
    dilution;
    inhalation;
    injury.

The risks from such sequences can be evaluated in two main ways, namely historical and analytical. In the historical approach, information from past incidents is used to predict the risks. *The Second Report of the Advisory Committee* contains information on some past incidents, and it derives a 'Mortality Index' to indicate the average number of fatalities per tonne of material released. This approach may be useful to devise a hazard rating for a material, but it is noticeable that the average index conceals a wide variation between cases and it is thus of questionable value for predicting individual situations. Other problems with the historical approach are the small number of cases and the incompleteness of information on cases, so it may therefore provide a rather poor statistical basis. This approach might be difficult to adapt for prediction in situations different from those already included by the accidents.

The alternative, analytical approach attempts to synthesize the risk on the basis of sequences outlined above. This approach is complex and requires assumptions to be made in the absence of data. Also, it may be difficult to select appropriate scenarios to include. It is, of course, possible to combine the approaches, and in practice this is what is done. The historical approach is used to provide information on the likelihoods of releases, while the analytical approach is used to predict consequences. To illustrate the approach, the example of bulk pressurized LPG is used. Installations of this type comprise the majority of the major hazards in Britain, and the risks from them are relatively straightforward to assess. The assessment may begin by listing the various possible releases, either by quantity (short release, e.g. tank burst) or by rate (long release, e.g. uncontrolled pipe-split). There is a continuous range of possible release, but this can usually be simplified by identifying obvious sub-divisions. For the LPG case we might have:

Event	*Probability*	*Consequences*
Minor flange or gland weeping	Quite likely	Not felt off-site
Pipework break	Rather unlikely, especially for major cases	Localized, but could extend off-site from major cases
Tank burst: BLEVE	Very unlikely	May be harmful at considerable distances off-site
Tank burst: UVCE (delayed ignition)	Extremely unlikely	May be harmful at considerable distances off-site
Tank burst: drifting gas clouds	Extremely unlikely	May be harmful at considerable distances off-site

It is now necessary to determine more precisely what are the probabilities and consequences of these events. Obviously there could be wide variations between individual plants and between events in each sub-division. For example, the effects from pipe-break might depend on: size of hole; duration before shut-off; whether liquid gaseous or two-phase; wind-speed; delay before ignition; dispersion to below flammable limits; type of combustion, and specific site features. To simplify the problem, assumptions are made to give an indication of the realistic outcome from the most severe event within a sub-division.

The consequences in terms of likelihood of injury are derived by first calculating the impact intensity of the heat or blast at a particular distance, then relating this to the vulnerability of the population at that distance. The possibility is noted that different types of building, having different populations, might give different degrees of protection from any given intensity.

The result of this process is a list of events and risks. A decision can then be made on which events are trivial in that no injury could result. For remaining events, the consequences are considered in conjunction with the likelihood, to determine the combined risk of release and injury. This completes the objective assessment.

It should be noted that this approach does not automatically rule out from consideration any type of source event, however unlikely. Even the largest, most unlikely events are included, so there is not necessarily any cut-off corresponding to a 'maximum credible accident'. However, attention is paid to the combined risks, which may be very small from an unlikely event, so that the largest events are not necessarily significant determinants of the overall risk. In practice, assessments may be based on one or two events which may thus appear to correspond to 'maximum credible accidents;' this implies that lesser events may be more damaging but they are so unlikely as to present negligible extra risk. For the LPG example, separation distance guidelines for the siting of the first category of development near existing installations tend to be based on the provision of substantial protection from BLEVE and UVCE; this automatically gives a very high degree of protection from pipe-break and lesser events.

A25.1.3 Assessment: types of development

It was indicated earlier that different types of building may have associated with them populations whose vulnerabilities differ. This may be of great importance in a siting judgement. HSE feels that it would be inappropriate to advise against all forms of new development near major hazards nor need new major hazards to be sited away from all existing buildings. Types of developments may be distinguished by various factors which relate to the risks, for example

(1) whether residential, workplace, recreational, shopping, etc.;
(2) length of time any individual may be present;
(3) number of people who may be present and duration of occupancy;
(4) ease of evacuation;
(5) inherent vulnerability of people, for example, elderly, disabled, children;
(6) physical factors, for example building height, materials of construction, etc.

On the basis of these factors, HSE identifies three main categories of development. The first consists of developments where users would be present for most of the time, or where large numbers could be present at any one time, or where people are particularly vulnerable. Examples include housing, shopping centres or very large retail outlets, multi-storey office blocks, etc. The second category consists of less sensitive developments and includes industrial developments with low employment density, warehouses, etc. HSE also identifies a third category containing special cases such as hospitals, schools and other particularly vulnerable developments, to which particular attention should be paid in siting judgements.

It is normally advised that planning control is only necessary in respect of the first and third categories of developments near major hazard installations. There are various mitigating factors associated with the second category, such that it would be difficult to argue that the risks to users justify inhibition of this type of land use. These factors could include ease of evacuation, low occupancy-time, fitness of population (e.g. adult workforce), small number of people, building protection or building not hazardous to occupants, etc.

A25.1.4 Summary of MHAU's advice

For LPG and similar flammable liquid gases, HSE recommends separation distance limits such that the consequences of minor releases at the limit would not be injurious, while the consequences of major releases (BLEVE, UVCE) would be unlikely to seriously injure more than a small fraction of the exposed population. In principle, unignited vapour clouds could travel to the limit, or even beyond it in unfavourable weather conditions, and people enveloped in a cloud would probably be seriously injured, but the risk to an individual from such a scenario is very low.

For chlorine, HSE recommends separation distance limits such that the consequences of major pipework failures would be unlikely to seriously injure more than a small fraction of the population downwind, in typical prevailing weather conditions. In unfavourable weather, or with larger releases from tank failure, people at greater distances could be injured, but the risk to an individual from such a scenario is very low.

A25.1.5 Presentation of advice

In presenting its advice, HSE attempts to give planning authorities clear guidance on the weight to be attached to the factor of safety. HSE tends to use one of three graded responses as follows:

Situation 1 (negligible risk): No significant reasons for refusing planning permission.

Situation 2 (marginal risk): The risks are very small and are not in themselves sufficient grounds for refusing planning permission, but they could be a factor against the development to add to any other adverse factors. This would apply near the outer limit of separation distance, or with small developments.

Situation 3 (substantial risk): While the probability of a serious incident is low, the consequences at the proposed development site could be serious. The safety issue should be a major factor and the planning authority is advised not to grant planning permission. If there were other factors which weighed strongly in favour of the application, HSE would seek to explain the technical assessment and level of risk in more detail before the planning authority's decision was made. (In exceptional cases of situation 3, where the planning authority was minded to grant permission contrary to the HSE's advice, HSE might consider whether to request a planning inquiry where the issues could be examined in detail in a public forum.)

It often happens that an initial unfavourable response from HSE leads to discussions of the scope for modifications to reduce the risk. Significant reduction may enable HSE to advise favourably. In other cases, HSE may give a conditional response, with advice on the use of planning conditions to ensure that the risk is reduced.

Appendix

Public Planning Inquiries

Contents

In a limited number of cases, a planning proposal involving a major hazard goes to a public inquiry. The inquiry will then normally hear technical evidence, which is likely to centre around the hazard assessments carried out by the parties. Experience shows that there are a number of problems associated with expert testimony at public inquiries.

A study of large public inquiries is given in *The Big Public Inquiry* by Sieghart (1979).

Accounts have been given of the public inquiries at Mossmorran by McGill (1981, 1982, 1983), Pheasant Wood by Petts (1985b) and at Canvey by Petts (1985a). A comparative review of the problems of expert evidence at public inquiries and proposals for their mitigation has been given by Petts, Withers and Lees (1986).

Public accident inquiries are discussed in Chapter 27.

A26.1 Mossmorran

It is usual in Scotland for planning applications for major oil-related developments to be called in for review by the Secretary of State. In the case of the application of Shell Expro to build a gas plant and of Esso Chem to build an ethylene cracker at Mossmorran together with associated facilities at Braefoot Bay, the minister decided on a public inquiry, which was held in 1977. The local planning authority (LPA) retained the consultants Cremer and Warner to produce an assessment of the hazards. The Health and Safety Executive (HSE) also gave its own assessment. These were the two main sources of technical evidence and neither opposed the development. Opposition came from local interest groups at Aberdour, Braefoot Bay and Dalgety Bay, who produced their own assessment. There was a delay of some 18 months after the inquiry closed until 1979 before the minister gave his approval. The delay was apparently caused in part at least by the issue of ignition of 'radio sparks', which was raised after the inquiry had ended.

The Mossmorran inquiry, which has been studied by McGill (1981, 1982, 1983), illustrated the difficulties of public inquiries on hazardous installations, particularly with regard to expert testimony. The amount of information on the plant limited the contribution of the HSE and severely restricted that of the objectors. The latter considered that the statutory authorities had not made available a sufficiently full hazard assessment and they were not satisfied that the objections made to the assessments presented received sufficient weight or that either the LPA or the HSE were sufficiently independent of government and industry. The LPA were clearly in favour of the proposals before they commissioned the consultant's report.

A planning application is concerned with the development of land. The extent to which a planning inquiry should cover marine activities is perhaps a grey area. The hazards from marine activities at Braefoot Bay were briefly considered in the consultant's report and the inspector did take some evidence on shipping movements in the estuary, but marine hazards were not thoroughly revealed. The objectors were not unnaturally more concerned with the level of risk than with its source and considered that insufficient attention was given to the marine hazards, which might exceed those from land-based activities.

The inquiry exemplified the problem of assessing the risk from a plant for which the completed design is not yet available. The first stage of planning permission is outline planning permission. At this point, the design of the plant is generally available as a feasibility study only. It is outline planning permission, however, which is the important stage and it is difficult thereafter to revoke permission. In this case since the detailed design of the plant had not been done when planning permission was applied for, the assessments which could be made were that much less detailed and the uncertainties in the risks assessed that much greater. The objectors evidently thought that an adequate estimate of the risks could not be made without a hazop study, although this cannot be done until a detailed design is available.

The inquiry did demonstrate, however, the effectiveness of a planning condition. Condition 24 of the planning permission eventually given required the companies to carry out hazop studies and major studies were carried out.

The consultant's report reviewed the various hazard scenarios and graded their likelihood in qualitative terms such as 'low', 'very low' and 'extremely low', but did not give a full assessment of individual and societal risks. The HSE evidence was qualitative. The lack of any full quantitative assessment was criticized by the interest groups, who emphasized that the Canvey study, a quantitative assessment and public report, was regarded by the HSE as a major step forward in hazard control, yet such an exercise was not done for Mossmorran. These groups were also critical of various apparent inconsistencies in the HSE approach. It was alleged that the HSE estimate of the maximum credible spill at Braefoot Bay was not consistent with that given for Canvey and that the HSE was recommending a cordon sanitaire at the gas plant but not at the marine terminal, where many of the hazards were. Some of the HSE's assessments of physical phenomena were challenged and the opposition was able to call expert witnesses of some academic standing. The safety distances acceptable to the HSE were said to be less than those required in certain other countries. The opposition groups produced some risk estimates which indicated that the likelihood of a multiple fatality accident at Aberdour/Dalgety Bay marine terminal was 10^{-4}/year as opposed to the estimate of 10^{-6}/year given by the consultants.

The consultant's report, despite the absence of a quantitative assessment, gave advice on risk criteria. This raised the question whether it is the expert's job not only to do the risk estimates but also to evaluate them. On the other hand there did appear to be some opposition groups would not have been too unhappy with an annual risk of 'one in a million' (10^{-6}/year).

After the inquiry had ended, the question was raised of the possible hazard of ignition of a release of flammables by 'radio spark' transmissions from the nearby naval transmitter at Crimond. The HSE undertook extensive work on this 'radio spark' hazard.

The inquiry also illustrates another very basic problem, that if the company makes no modifications to its proposals as a result of objections posed, it appears to ride roughshod over the opposition, while if it does, it appears to be incompetent.

The inquiry and its aftermath give an impression of imbalance in the treatment of the hazards. In particular, the question of hazards associated with radio sparks received a disproportionate amount of attention relative to the hazards at the marine terminal. Despite this concession to the opposition groups, they were clearly dissatisfied with the inquiry.

A26.2 Pheasant Wood

The Pheasant Wood inquiry, which has been studied by Petts (1985b), on proposed housing development near to ICI chlorine and phosgene storages arose when the HSE asked the Secretary of State to call in the proposal for review after the LPA had indicated its intention to grant planning permission. The HSE gave its hazard assessment. The developer retained Cremer and Warner to present an alternative assessment, while ICI, although not directly involved, chose to offer its own assessment. All these parties presented technical evidence. The HSE's assessment included estimates of both frequencies and consequences of events, but did not combine these together to give individual and societal risks. They were criticized by the inquiry assessor and by ICI for this limitation. On the other hand, the other parties, although they did estimate these risks, did not always give the full basis of their estimates. Another point at issue between the HSE and the ICI evidence was some of the data used for the frequency of release. Whereas the HSE had to rely on generic data, the company was able to use data from its own installations which, depending on the viewpoint, were less pessimistic or more optimistic. The appropriateness of the gas dispersion models used was also an issue between the parties. The inspector found against HSE's case and in favour of granting planning permission. A feature of the Pheasant Wood inquiry which distinguishes it from those at Mossmorran and at Canvey was the low level of public interest.

A26.3 Canvey

The Canvey complex of oil refineries, chemical works, etc., has been the subject of several inquiries and hazard assessments, which have been described by Petts (1985a). The period 1965–73 saw a spate of planning applications and three public inquiries for oil refinery development. The economic pressures were clearly strong. The inquiry inspector's recommendations were twice overruled by the minister in favour of development. At the same time, the level of local concern over the hazards and environmental impact of the Canvey complex was rising and led to the opening, in 1975, of an inquiry into the possibility of revoking the planning permission granted to United Refineries Ltd (URL) in 1971. The technical assessor's report discussed the hazards in qualitative terms. No quantitative hazard assessments were presented.

One of the assessor's recommendations was a study of the possible hazardous interaction between the various installations at Canvey. Acting on this, the minister asked the HSE to look into the matter and the HSE commissioned a study from SRD, the First *Canvey Report*.

With the publication of this report, the minister was in a position to reopen the inquiry on the revocation of planning permission for URL. The inquiry was held in 1980 and considered both the bearing of the *Canvey Report* on the URL project and also the validity of the report itself, the parties being essentially the HSE and the objectors. The only full hazard assessment presented was that of the HSE in the form of the report. The report had not been commissioned specifically for the inquiry, but nevertheless there was for the first time available to an inquiry in Britain a full assessment of individual and societal risks.

One of the main hazards considered was a marine spill of LNG or LPG at the British Gas methane terminal. Disagreements arose over the estimates both of the frequency and the magnitude of this hazard. While the Port of London Authority (PLA) considered that the report overestimated the frequency of ship collision, the objectors presented graphic qualitative evidence of the problems of tanker handling. Estimates of the distance travelled by the flammable gas cloud before it fell to its lower flammability limit varied widely from 1 km to 28 miles.

Doubt was cast on some of the HSE's proposals for mitigating the hazards. The practicality and effectiveness of the water spray barrier against an ammonia cloud was challenged. PLA witnesses stated that the 8 knot speed limit proposed in the Scheduled Area was not practical.

The estimated risks were also matter for debate. The risk values were relatively high. For example, the calculated fatality risk attributed to the URL extension was comparable with the national fatality risk at work. The inspector considered the risks in some areas unacceptable.

Although the *Canvey Report* received praise and its overall approach was not challenged, it had certain deficiencies which detracted from it. The text was very disjointed, there were discrepancies between text and tables and there were some inaccuracies.

The inspector recommended that the URL planning permission should not be revoked, but only if the risk from the British Gas methane terminal were reduced by installing a ring of igniters at the periphery or by closure.

In 1981, the Second *Canvey Report* appeared. In this reassessment, which used revised failure data, more refined hazard models and more accurate population profiles and which took into account changes made on the installations, the assessed risks were less, some by an order of magnitude.

In 1982, another public inquiry was held, this time on the possible discontinuance of the British Gas methane terminal. British Gas produced a full hazard assessment, while the two *convey Reports* formed the basis of the HSE's evidence. The British Gas assessment used by intent broadly realistic estimates, the HSE conservative ones. The risks estimated by British Gas were lower, in some cases by two orders of magnitude. Realism rather than conservatism was not the only reason for this. The British Gas estimates of failure rates were lower and its gas dispersion estimates gave lower travel distances. The inspector stated that he found HSE's evidence much easier to understand and that he preferred their conservative approach, and he put some value on the independence of the HSE.

A number of expert witnesses were called by the objectors, notably the Castle Point District Council and the Castle Point Refineries Resistance Group. In many cases, their evidence failed to stand up to cross-examination due to weak hypotheses on accident scenarios, oversimplified assumptions, incorrect hazard models, misunderstanding of the work of others, especially the Second *Canvey Report*, and numerical errors. The technical assessor played an active role in this inquiry both in advising the inspector and in producing the report.

The inspector recommended against closing the British Gas terminal or requiring igniters.

A26.4 Sizewell

The inquiry on the proposal to construct a PWR at Sizewell B began in January 1983 and ended in February 1985. This is by any standards a 'big' public inquiry and the hazards of a nuclear reactor are one of the topics on which much expert testimony has been heard. In the present context, the inquiry is of interest for its influence on the development of the form of such inquiries; for its influence on the formulation of risk criteria; and for the evidence given on some of the technical safety issues, particularly on rare events.

An important feature of the inquiry was the use of counsel to the inquiry. The inquiry also saw the increased use of informal 'side' meetings between experts at which issues can be clarified and misunderstandings removed.

Another feature of the inquiry is that a preconstruction safety report was available before the inquiry from the CEGB, although many design aspects remained unresolved.

With regard to risk, the Inspector suggested that where risks of the kind considered are accepted they are better described as 'tolerable' rather than 'acceptable' and encouraged the HSE to develop risk criteria. Such criteria have subsequently been published by the HSE (1988b, 1989d).

Among the many issues on hazards which the inquiry illustrates is that of the very rare event. A crucial accident scenario for a PWR is failure of the reactor pressure vessel (RPV). Such a failure is generally agreed to be a very rare event, but it may have very serious consequences. Estimation of the frequency of an event which has a high hazard potential but is very infrequent, perhaps scarcely credible, is one of the most intractable problems in hazard assessment. The inquiry is instructive not only because there were differences between experts in the methodology of estimation of the RPV failure frequency but also because there was scope for differences of perception of what was eventually established.

Evidence on the estimation of the RPV failure frequency was given for the CEGB by Dr B. Edmundson, for the Greater London Council by Technica Ltd and for the Suffolk Local Authorities by Professor Kussmaul from Germany. Another expert, Professor T.A. Kletz, gave evidence at the invitation of the inspector. On the basis of historical pressure vessel failure data Technica estimated the RPV failure rate at 1×10^{-6}/year. This figure was derived from the crude figure of 3.2×10^{-6}/year obtained from the historical data, and was intended to give credit for improved technology embodied in the RPV, but to be nevertheless a realistic rather than a conservative estimate, as the witnesses were at pains to point out. The CEGB derived their estimate of RPV failure rate using engineering principles, such as fracture mechanics, to determine the frequency of the failure modes which they considered credible, and obtained for catastrophic vessel rupture with generation of missiles an estimate of 2.4×10^{-9}/year. Professor Kussmaul preferred the CEGB's approach to that of Technica but advocated an alternative method of pressure vessel construction so as to minimize the risk of weld failure. This construction was not accepted by the CEGB and after further discussion between the parties Professor Kussmaul accepted the CEGB's approach subject to certain procedures which he specified and to which they agreed. As a result, the Suffolk Local Authorities withdrew their objections on grounds of safety, since they accepted Professor Kussmaul's advice that the risks were 'so low as to be incredible'.

There were nearly two orders of magnitude between the CEGB and Technica estimates of the RPV failure rate. The Technica estimate was in fact based on a single historical pressure vessel failure, which the CEGB regarded as so unusual as to be inconceivable on their vessel. However, even if no failure has occurred historically, it is still possible to make a statistical estimate by using the number of failure-free years and assuming that a failure is just about to occur. It therefore makes little difference to the number obtained whether the number of failures is one or zero. More important was the difference between the parties on whether the estimate should be based on historical statistics or engineering principles. Technica argued that even if the single historical failure was a bizarre one, such events cannot be completely discounted, that this stood in for the whole set of bizarre events which might occur, and that the method based on the historical data was the appropriate one to use.

In his cross-examination, counsel for the CEGB sought to identify assumptions in the Technica estimate. For Technica Dr. R.A. Cox stated clearly that the figure of 1×10^{6}/year was a 'best estimate', intended as realistic rather than conservative. However, counsel drew attention to the fact that in its written evidence Technica had at one point referred to this figure as an 'upper bound'. Dr P.J. Kayes for Technica then explained that what was meant by this was that the figure was an 'upper bound on the type of studies that would claim RPV failure to be incredible'. Counsel then asked: 'Is it intended to provide an upper bound to the likelihood of RPV failure?' and the witness replied: Yes, it is, as a best estimate'. Thus Technica were liable to believe that their figure was accepted as a realistic estimate, the CEGB that it had been conceded to be conservative.

In cross-examination, Professor Kletz commented that the two methods should not be seen as necessarily in conflict. A difference between the two by orders of magnitude was understandable. He did say, however, that while a large improvement in the reliability of the CEGB vessel over historic vessels could be expected, he had some personal scepticism whether any man-made artefact could provide such a low figure as the CEGB was claiming. In the case of the RPV the failure frequency was so low that he felt there was some justification for making allowance as Technica proposed for bizarre events and referred to possible failure due to previously unknown metallurgical phenomena. When cross-examined by one of the assessors, he agreed that his scepticism regarding very low numbers applied to a very low figure for a single event rather than one obtained as the product of the figures for a chain of events.

Thus, while the differences of opinion over points raised by Professor Kussmaul were largely settled by discussion outside the formal proceedings and the main findings reported back to the inquiry, the differences arising from the Technica evidence were not resolved at the side meetings and the parties were liable to interpret the evidence given in the inquiry cross-examination as supporting their particular positions.

A26.5 Expert Evidence

The foregoing account of some of the principal inquiries which have been held on hazardous installations indicates that there are a number of problem areas. These problems have been reviewed and proposals made for mitigating them by Petts, Withers and Lees (1986).

A26.5.1 Problems of adversarial forum

A view commonly expressed by technical experts is that the adversarial situation of a public inquiry is not an appropriate means of examining technical issues. Many experts find the adversarial process unfamiliar and intimidating and regard it as an inappropriate means of arriving at the truth on technical matters. The adversarial process tends to lead to adoption of rigid, defensive positions.

For interest groups opposed to a development, the adversarial forum of an inquiry has the advantage that they can examine the developer's case, but can be intimidating to them also and it presents considerable difficulties for groups with few resources.

A26.5.2 Problems with hazard assessments

Many of the problems of expert testimony at public inquiries on process installations centre round hazard assessment. Most of these difficulties can be grouped under one or other of the following heads:

(1) obscurity;
(2) incompleteness;
(3) inconsistency.

Obscurity

There may be inherent difficulties in the subject matter or in its presentation.

Thus at the Sizewell inquiry the debate on engineering features of the pressure vessel was difficult to follow without engineering drawings. At the Canvey inquiry, the inspector himself had difficulties with the hazard assessment by British Gas and felt that the mode of presentation was more appropriate to a learned society than an inquiry.

Fundamentally difficult matters are typified by the arguments at Sizewell over the frequency of rare events and over probabilistic risk analyses.

Incompleteness

Information may be incomplete for many reasons. The engineering design may not be complete by the time of the inquiry, there may be deliberate selectivity in the hazards examined and there may be simple failure to identify all the hazards.

Thus at the Mossmorran and Sizewell inquiries much plant-specific information was unavailable because the projects were still in the feasibility stage. Estimates were therefore conceptual and based on generic data. This is likely to be a common situation.

Selectivity is exemplified by Mossmorran, where the objectors expressed concern about hazards at the port which seemed to have received less attention than the gas plant itself. Again at Mossmorran, there were objections to the exclusion of aircraft crashes. Later the possible hazard of ignition from radio sparks was raised and led to a separate investigation.

Inconsistencies

Some inconsistencies appear at an inquiry simply because of the lack of an agreed structure and methodology for the hazard assessment. There are also differences in the particular models used and in the basic approach to probability estimation.

Examples of differing structure and methodologies appeared at Pheasant Wood, where the assessment by the HSE did not provide any estimates of individual or societal risk, while those of the consultants and of ICI did. The HSE case was based on generic data, while the ICI case was based on plant-specific data.

At Canvey there were wide differences in the results obtained from different gas dispersion models. There have also been wide differences in the relations describing injury and damage. This is illustrated by the *Rijnmond Report,* which, although not a document presented to an inquiry, represents the type of hazard assessment which might be submitted. The report revealed ten-fold differences in estimates of the lethal concentrations of chlorine.

Such differences and uncertainties usually result in judgements being made about the likely margin of error. These judgements may occur at a number of points in the chain of calculations which make up the assessment. They may be optimistic or pessimistic.

In general, industry is anxious that the risks should not be exaggerated and presses for realistic assessments wherever possible. It may seek to avoid the use of numerical estimates of risk altogether where the confidence bounds are very wide. The HSE, on the other hand, is bound in the public interest to take a fairly cautious view and may be expected to incline towards the use of values which are to some degree conservative. In the risks assessed for the methane terminal at Canvey, the HSE and British Gas sometimes differed by a factor of a hundred, partly due to the difference between realism and conservatism.

Examples of the use of differences in approach to probability estimation were demonstrated at Sizewell, where the objectors based their estimate of pressure vessel failure rate on historical data and the CEGB its estimate on engineering considerations, the latter thereby obtaining for the event in question a frequency lower by some two orders of magnitude.

It should be recognized that public opposition to an industrial development may in some cases be so strong as to influence the character of the presentation and examination of the hazard assessments. At Pheasant Wood there was little public interest, whereas at Mossmorran this interest was strong and organized.

A26.5.3 Availability of information

An essential requirement of the parties to an inquiry is the availability of information. This information needs to be of the appropriate kind and to be provided at the right time. This requirement would in large part be met if the company makes available at the outset of the inquiry a form of open conceptual safety case.

The LPA may wish to commission an independent report from a consultant, as well as seeking advice from the HSE.

The use of open safety cases presented in a uniform style would greatly assist the LPAs to become familiar with the problems posed by hazardous installations and to instruct consultants.

The HSE may also provide for the inquiry inspector an independent hazard assessment by which he can evaluate the evidence of the other parties.

Twenty-eight days before the inquiry the LPA is required to produce a written statement. It is only the LPA which has this obligation.

A26.5.4 Parties to inquiry

The LPA will always be a party to a planning inquiry. There is no general requirement that staff from other government bodies (such as the HSE) should appear in person. In practice they often do.

The parties will often be represented by legal counsel at the inquiry. An innovation at Sizewell was the appointment of counsel to the inquiry itself. This appears to have been of great assistance to the inspector and to have helped other parties to clarify issues. In an adversarial process, the investigatory role of such counsel appears of great value, particularly for technically complex projects.

The part played by the HSE at an inquiry needs to be seen in the context of its wider and ongoing role in the control of hazards. In order to safeguard this role, it is desirable that as far as possible the HSE should appear as an adviser rather than a protagonist and the situation where the HSE is the instigator of an inquiry is to be avoided as far as possible.

It is appropriate that at the outset of an inquiry the HSE be invited to state its role, the legislation under which it operates and the limits of its powers, that it define the set of principles by which it judges the nature of the risk and the relevant safety criteria required by the HSWA as enforced by the HSE. It may also indicate its expectations of the ability of the developer to meet these standards, while leaving it to the inquiry to balance these expectations with those of others, and with other relevant factors.

Many experts are called by objectors. The problems experienced at past inquiries have often centred around disagreements between these experts and others. It is desirable that these experts play their full part in the formal and informal meetings described below. In this way, issues can be clarified and difficulties which have arisen in the past avoided. Another class of witness is those called by the inspector, but these appear to present fewer problems.

A26.5.5 Arrangements at inquiry

A large inquiry usually has a formal preliminary meeting presided over by the inspector at which a detailed set of objectives, procedures and timetable are developed from the terms of reference. Such a meeting, which largely determines the subsequent course of the inquiry, is essential for large, technically complex projects.

The normal procedure in a public inquiry is to hear evidence by party rather than by issue, with the project's proposer having the final right of reply. This results in safety evidence being interspersed with other evidence on other topics, and not taken in its logical order. An exception tends to be made in big inquiries such as Sizewell, where hearing may be by issue. In general, hearing by issue suits the large organizations, who have little difficulty in making experts available on each issue as it arises. It may, however, create problems for smaller bodies with limited resources.

As described above, there has been some criticism of the adversarial approach inherent in public inquiries. In eyes of the public, however, it remains a safeguard, albeit imperfect, against concealment and is an important factor in legitimizing the inquiry process.

The problem of dealing with expert evidence in an adversarial forum may be mitigated by the use of non-adversarial side meetings between experts. Some of these may be formal meetings with minutes kept which are part of the inquiry record.

Appendix 27

Standards and Codes

Contents

Standards and codes of practice are one of the principal means by which experience of problems and their respective solutions is transmitted and fundamental to recognized and generally accepted good industrial practice. The production of a code is normally undertaken by a group of experienced practitioners under the aegis of an appropriate organization. The code represents the consensus of this group on what constitutes good practice. There is usually some degree of consultation with the parties who will use the code.

There are a vast number of codes produced by a variety of bodies and the status of a code depends on the body which promulgates it. Inevitably a code becomes out-of-date as technology changes, so that a process of continuous revision is necessary. A 5-year update is most commonly-suggested.

The philosophy commonly adopted in writing a new code is to define limited objectives and to get the code finished, recognizing that further revision will be necessary in due course, rather than to seek to produce a definitive work. Standards and codes of practice normally use a specialized and defined terminology.

Mandatory requirements, that is, those that it is essential to satisfy, are expressed by the use of the word 'shall'. The word 'must' is used when an absolute imperative arises, for example when safety considerations apply.

Non-mandatory requirements, that is, those that are recommended or desirable are usually expressed by the use of the auxiliary 'should'. Should implies a recommendation based upon the judgement of experienced people but recognizes that some discretion is appropriate in special circumstances.

A27.1 Globalization of Standards

The ever increasing world of international trade has created a need for internationally accepted standards. When the large majority of products or services in a particular business or industry sector conform to International Standards, a state of industry-wide standardization can be said to exist. This is achieved through consensus agreements between national delegations representing all the economic stakeholders concerned – suppliers, users, government regulators and other interest groups, such as consumers. They agree on specifications and criteria to be applied consistently in the classification of materials, in the manufacture and supply of products, in testing and analysis, in terminology and in the provision of services. Hence, International Standards provide a reference framework, or a common technological language, between suppliers and their customers, thereby facilitating trade and the transfer of technology.

International Organization for Standardization (ISO) together with the International Electrotechnical Commission (IEC) and International Telecommunication Union (ITU) has built a strategic partnership with the World Trade Organization (WTO) with the common goal of promoting a free and fair global trading system. The political agreements reached within the framework of the WTO require underpinning by technical agreements. ISO, IEC and ITU, as the three principal organizations in international standardization, have the complementary scopes, the framework, the expertise and the experience to provide this technical support for the growth of the global market.

ISO is the world's largest developer of standards. ISO is a network of the national standards institutes of 148 countries, on the basis of one member per country, with a Central Secretariat in Geneva, Switzerland, that coordinates the system. ISO is a non-governmental organization, its members are not delegations of national governments. ISO occupies a position between the public and private sectors. This is because many of its member institutes are part of the governmental structure of their countries, while other members have their roots uniquely in the private sector, such as industry associations and technical societies.

Therefore, ISO is able to act as a bridging organization in which a consensus can be reached on solutions that meet both the requirements of business and the broader needs of society, such as the needs of stakeholder groups like consumers and users. The vast majority of ISO standards are highly specific to a particular product, material or process. However, the ISO 9000 and ISO 14000 standards have earned a worldwide reputation are known as 'generic management system standards'. 'Generic' means that the same standards can be applied to any organization, large or small, product or service, and whether it is a business enterprise, a public administration or a government department. 'Management system' refers to what the organization does to manage its processes, or activities. 'Generic' also signifies that no matter what the organization is or does, if it wants to establish a quality management system or an environmental management system, then such a system has a number of essential features that are spelled out in the relevant standards of the ISO 9000 or ISO 14000 standards. The US OSHA process safety management regulation is another example of the performance-based philosophy defined in the generic management system standards.

A27.1.1 Conformity assessment

Conformity assessment means checking that products, materials, services, systems or people measure up to the specifications of a relevant standard. Many products require testing for conformance with specifications or compliance with safety, or other regulations before they can be put in the stream of commerce. Even simpler products may require supporting technical documentation that includes test data. ISO has developed many of the standards against which products are assessed for conformity, as well as the standardized test methods that allow the meaningful comparison of test results so necessary for international trade.

ISO itself does not carry out conformity assessment. ISO develops ISO/IEC guides and standards to be used by organizations that carry out conformity assessment activities. The voluntary criteria contained in these guides and standards represent an international consensus on what constitutes best practice. Their use contributes to the consistency and coherence of conformity assessment worldwide.

A27.2 Where to Find Information on Standards

There are several hundred thousand standards and technical regulations in the world containing special requirements for a particular country or region. Finding information about these, or about related conformity assessment activities, can be a heavy task. ISONET, the SO Information Network, can ease the problem. This is a worldwide network of national standards information centres, which have cooperatively developed a system to provide rapid access to information about standards, technical regulations and testing and conformity assessment activities in operation around the world. The World Trade Organization's Agreement on Technical Barriers to Trade (WTO/TBT) typically establishes a national enquiry point to answer questions on regulations and standards in each country, the ISONET and WTO enquiry points are the same. WSSN is a network of publicly accessible Web servers of standards organizations around the world. It contains links to international, regional and national standardization bodies, and also to other international and regional organizations that develop standards in their specialized subject area; available at http://www.wssn.net/WSSN/index.html.

Leading national standards institutions, which co-operate with ISO are:

- British Standards Institution (BSI);
- American National Standards Institute (ANSI);
- Deutsches Institut fur Normung (DIN);
- Verein Deutscher Ingenieure (VDI);
- Association Francaise de Normalisation (AFNOR);
- Comite de Normalisation Europeen (CEN);
- Comite de Normalisation Europeen Electrotechnique (CENELEC).

Some technical associations that generate standards and codes of practice relevant to safety and loss prevention are listed below.

- American National Standards Institute (New York);
- American Industrial Hygiene Association (Fairfax, VA);
- American Petroleum Institute (Washington, DC);
- American Society of Civil Engineers (New York);
- American Society of Heating, Refrigerating and Air-Conditioning Engineers (Atlanta, GA);
- American Society of Mechanical Engineers (New York);
- American Society for Quality Control (Milwaukee, MI);
- American Society for Testing and Materials (Philadelphia, PA);
- American Welding Society (Miami, FL);
- British Chemical Industry Safety Council;
- British Compressed Gases Association (London);
- Chemical Industry Safety and Health Council (London);
- Det Norske Veritas (Stavanger, Norway);
- Imperial Chemical Industries Pic;
- Institute of Electrical and Electronic Engineers (New York);
- Institute of Petroleum (London);
- Instrument Society of America (Research Triangle Park, NC);
- International Chamber of Shipping (London);
- International Maritime Organization (London);
- Liquefied Petroleum Gas Industry Technical Association (London);
- National Fire Protection Association (Quincy, MA);
- Oil Companies International Marine Forum (London);
- Society of International Gas Tanker and Terminal Operators (London);
- Tubular Exchangers Manufacturers Association;
- Underwriters Laboratories (Northbrook, IL);
- Verein Deutscher Ingenieure.

A27.2.1 Among the first safety codes

Modern fire safety codes and standards, and in particular those developed by the National Fire Protection Association (NFPA), trace their origins to the nineteenth-century development of automatic sprinklers. From the beginning, sprinklers performed properly as extinguishing devices; however, they were originally installed in so many different ways that their reliability was uncertain.

From the beginning, the mission of the NFPA is to reduce the burden of fire and related hazards on the quality of life. The NFPA mission today is accomplished by advocating scientifically based consensus codes and standards, research and education for fire and related safety issues. NFPA's National Fire Codes are developed by technical committees staffed by over 6000 volunteers, and are adopted and enforced throughout the world. NFPA functions as a non-profit membership organization with more than 68,000 members worldwide.

Development of NFPA standards follow the original principles still followed today by NFPA Technical Committees:

'To bring together the experience of different sections and different bodies of underwriters, to come to a mutual understanding, and, if possible, an agreement on general principles governing fire protection, to harmonize and adjust our differences so that we may go before the public with uniform rules and conditions which may appeal to their judgment is the object of this Association.'

Despite the term 'National' in NFPA, the name sometimes seems to imply the lack of international involvement.

1984	Effect of hydrostatic retesting on stress corrosion cracking by Barlo, Eiber, Berry and Fessler	40
1984	The effect of random seas on pipeline stability, vol. 1, Wave/soil simulations and simplified design methods by L.E. Borgman and R. Hudspeth	41
1984	The effect of random seas on pipeline stability, vol. 2, Finite element modeling of pipeline response by L.E. Borgman and R. Hudspeth	42
1984	Critical evaluation of multiphase pipeline calculation methods by Gregory and Fogarasi	43
1985	Crank shaft stress reduction through improved alignment practices by Smalley and Palazzolo	44
1986	NOT needs for pipeline integrity assurance by Kiefner, Hyatt and Eiber	45
1986	Study of new joining processes for pipelines by G.R. Saltera and J. Weston	46
1986	Underground tanks in the natural gas industry	47
1987	Criteria to stop active pit growth by Thompson, Beavers and Han	48
1987	Investigation of sulfide-stress cracking at pipe seam welds by H.J. Clalone and D.N. Williams	49
1988	Crack growth behavior and modeling by T.K. Christman and F.W. Brust	50
1988	Effect of water chemistry on internal corrosion rates in offshore natural gas pipelines by D.W. Shannon *et al.*	51
1988	Emergency shutdown systems (compressors)	52
1988	Field weldability of high strength pipeline steels by D.N. Noble and R.J. Pargeter	53
1988	Heat affected zone toughness in heavy-wall pipe by A.G. Glover and D.B. Varo	54
1988	Operating safety in the natural gas industry	55
1988	Prediction of SCC susceptibility based on mechanical properties of line pipe by T.K. Christman	56
1988	Proof testing on pre-hot-tap branch connections by M. Rosenfeld and W.A. Maxey	57
1988	Relief valves in compressor stations	58
1988	A review of gas industry pipeline coating practices by S. Nunez *et al.*	59
1988	Safety factors in the assessment of realistic defects in pipeline welds by A.P. Hodgson and R.H. Leggatt	60
1989	Criteria for hot tap welding – further studies by Threadgill and Cola	61
1989	Evaluation of the capabilities of advanced AE monitoring of buried natural gas transmission pipe and AE evaluation of a known colony of SCC by F.B. Stulen	62
	Not used	63
1989	Remote field eddy current crack and defect detection by W. Lord	64
1989	Review of procedures for welding onto pressurized pipelines by P. Threadgill and M. Cola	65
1989	State-of-the-art methods for multiphase flow pipelines by C.J. Crowley *et al.*	66
1990	Cathodic protection anodes	67
1990	Effect of loading on the growth of deep stress corrosion cracks by J.A. Beavers *et al.*	68
1990	Methods for prioritizing pipeline maintenance and rehabilitation by J.F. Kiefner, P.H. Vieth *et al.*	69
1990	Remote field eddy detection of stress corrosion cracking, Phase I by J.B. Nestleroth	70
1991	Development of an ultrasonic stress corrosion cracking detection vehicle by C.W. Pope *et al.*	71
1991	Development and validation of a ductile flaw growth analysis for gas transmission line pipe B.N. Leis *et al.*	72
1991	Evaluation of nondestructive inspection methods for welds made onto in-service pipelines, I and II by W.A. Bruce and B.W. Kenzie	73
1991	A guide to controlling natural gas in emergencies	74
1991	Guidelines for analyses of fire protection and emergency response based on 49 CFR Part 193	75
1991	Optimizing techniques for CTOD testing of girth welds in line pipe by McGaughy and Gordon	76
1991	Technology of submersible remotely operated vehicles by F.R. Busby	77
1992	Criteria for dent acceptability of offshore pipelines by J.R. Fowler	78
1992	Development of a ductile pipe fracture model by G. Buzichelli, M.H. Kanninen *et al.*	79

1992	Development of optimized nondestructive testing inspection methods for weld made onto in-service pipelines, III by W.A. Bruce and B.W. Kenzie	80
1992	Development of simplified weld cooling rate models for in-service pipelines by M.J. Cola *et al.*	81
1992	Diverless pipeline repair clamp, Phase I by J.E. Miller and B. Knott	82
1992	Diverless pipeline repair clamp, Phase II by J.R. Fowler *et al.*	83
1992	Fracture behaviour of girth welds containing natural gas defects: comparison with existing workmanship standards by R. Denys	84
1992	Fracture behaviour of girth welds containing natural gas defects: effect of weld metal yield strength by R. Denys	85
1992	Historical manufactured gas plant sites: use of risk assessment in the development of remedial target concentrations	86
1992	Remote field eddy detection of stress corrosion cracking, Phase II by J.B. Nestleroth	87
1992	Spatial density of stress corrosion cracks in line pipe steel by R.N. Parkins *et al.*	88
1992	A study of processes for welding pipelines by J. Weston	89
1992	Subsea pig recovery concepts by H.O. Mohr	90
1993	Diver-assisted pipeline repair manual by H.O. Mohr	91
1993	Effect of weldment property variations on the behavior of line pipe by R.J. Dexter *et al.*	92
1993	Repair weld residual stress by T.C. McGaughy	93

Pipeline Incident Reports

1977	Analysis of the Office of Pipeline Safety Annual Report data for natural gas distribution companies 1970 through 1975 by J.F. Hefner and R.B. Smith	94
1981	Analysis of the Office of Pipeline Safety Operations 1970–78 Reportable Incident Data for the NG distribution companies by D.N. Gideon	95
1981	Analysis of the Office of Pipeline Safety Annual Report data for natural gas distribution companies by D.N. Gideon and R.B. Smith	96
1984	An analysis of reportable incidents for natural gas transmission and gathering lines 1970 through 1981 by Kramer, Gideon and Smith	97
*c.*1986	An analysis of reportable incidents for natural gas transmission and gathering lines: 1970–84 by Jongs, Kramer and Gideon and Smith	98
1992	An analysis of reportable incidents for natural gas transmission and gathering lines June 1984 through 1990 by R.J. Fiber and D.J. Jones	99
1992	DOT distribution, transmission and gathering incident report data since 1984 and Annual Report data for 1990	100

Annual series

Survey of Underground Gas Storage Facilities in the US and Canada	101

American Industrial Hygiene ssociation

(Fairfax, VA)

Year	*AIHA Press Publications*	*Item*
1970–	Ergonomics Guides (Annual Series)	1
1975	Basic Industrial Hygiene: A Training Manual	2
1977–	Non-ionizing Radiation Guides (series of three titles)	3
1980–	Workplace Environmental Exposure Level Guides (WEELs) (AIHA Workplace Environmental Exposure Levels Committee – Annual Series)	4
1983	Work Practices Guide for Manual Lifting by NIOSH	5
1984	Arc Welding and Your Health	6
1984	Engineering Field Reference Manual	7
1985	Biohazards Reference Manual	8
1985	Manual of Recommended Practice for Portable Direct-Reading Carbon Monoxide Indicators (AIHA Gas and Vapor Detection Systems Committee) ed. by Patrick R. Frazee	9
1986	Noise and Hearing Conservation Manual ed. by E.H. Berger, W.D. Ward, J.C. Morrill and L.H. Royster	10
1987	Occupational Exposure Limits – Worldwide by W. Cook	11
1988–	Emergency Response Planning Guidelines (Annual Series)	12
1988	Hygienic Guides (series of four sets)	13
1988	Quality Assurance Manual for Industrial Hygiene Chemistry	14
1989/ 1993	Manual Material Handling: Understanding and Preventing Back Trauma (AIHA Ergonomics Committee) ed. by K.H.E. Kroemer, J.D. McGlothlin, and T.G. Bobick	15
1989	Odor Thresholds for Chemicals with Established Occupational Health Standards (TRC Environmental Consultants under contract to AIHA)	16
1990	Chemical Protective Clothing, vols 1–2, ed. by J.S. Johnson and K.J. Anderson	17
1990	Computers in Health and Safety ed. by G. Rawls	18
1990	LOGAN Workplace Evaluation System by Dupont	19
1990	Safety Auditing: A Management Tool by D.W. Kase and K.J. Wiese	20
1990	The Practitioner's Approach to Indoor Air Quality Investigations: Proceedings of the Indoor Air Quality International Symposium (AIHA Indoor Environmental Quality Committee) ed. by D.M. Weekes and R.B. Gammage	21

1991	A Strategy for Occupational Exposure Assessment by N.C. Hawkins, S.K. Norwood and J.C. Rock	22
1991	Industrial Ventilation Workbook, 2nd ed., by D.J. Burton	23
1991	Laboratory Ventilation Workbook by D.J. Burton	24
1991	Respiratory Protection: A Manual and Guideline, 2nd ed., ed. by C.E. Colton, L.R. Birkner and L.M. Brosseau	25
1992	Occupational Exposure, Toxic Properties, and Work Practice Guidelines for Fiber Glass by J.R. Bender, J.L. Konzen and G.E. Devitt	26
1993	Direct-Reading Colorimetric Indicator Tubes Manual, 2nd ed., ed. by J. Perper and B. Dawson	27
1993	Dynamic Measures of Low Back Performance, an Ergonomics Guide by W.S. Marras, J.D. McGlothlin, D.R. McIntyre, M. Nordin and K.H.E. Kroemer	28
1993	IAQ and HVAC Workbook by D.J. Burton	29
1993	Manual of Recommended Practice for Combustible Gas Indicators and Portable Direct-Reading Health Survey Meters, 2nd ed.	30
1993	Manual of Recommended Practice for Combustible Gas Indicators and Portable Direct-Reading Hydrocarbon Detectors, 2nd ed., ed. by C.F. Chelton	31
1993	Responding to Community Outrage: Strategies for Effective Risk Communication by P.M. Sandman	32
1993/ 1996	Sampling for Environmental Lead (AIHA Ad Hoc Committee on Sampling for Environmental Lead)	33
1993	The Industrial Hygienisfs Guide to Indoor Air Quality Investigations	34
1993	The Industrial Hygienist's Guide to Indoor Air Quality Investigations (AIHA Indoor Environmental Quality Committee) ed. by P.J. Rafferty	35
1994	An Ergonomics Guide to VDT Workstations by C. Grant and M. Brophy	36
1994	Cumulative Trauma Disorders of the Hand and Wrist, An Ergonomics Guide by T.J. Armstrong and E.A. Lackey	37
1994	Industrial Hygiene Auditing: A Manual for Practice by A.J. Leibowitz	38
1994	Radio-Frequency and Microwave Radiation, 2nd ed.	39
1994	The American Industrial Hygiene Association: Its History and Personalities, 1939–1990 ed. by G.D. Clayton and F.E. Clayton	40
1995	Biosafety Reference Manual, 2nd ed. (AIHA Biosafety Committee)	41
1995	Exploring the Dangerous Trades: The Autobiography of Alice Hamilton	42
1995	Extremely Low Frequency (ELF) Electric and Magnetic Fields	43
1995	Hazard Communication: An AIHA Protocol Guide	44
1995	Inorganic Lead Guidance Document by L.C. Hearn, Jr.	45
1995	Laboratory Chemical Hygiene: An AIHA Potocol Guide	46
1995	Particle Sampling Using Cascade Impactors: Some Practical Application Issues (AIHA Aerosol Technology Committee) ed. by J.Y. Young	47
1996	An Ergonomics Guide to Hand Tools (AIHA Ergonomics Committee) by R.G. Radwin and J.T. Haney	48
1996	An International Review of Procedures for Establishing Occupational Exposure Limits (Chemical Manufacturers Association and AIHA)	49
1996	Field Guide for the Determination of Biological Contaminants in Environmental Samples (AIHA Biosafety Committee) ed. by H. K. Dillon, P.A. Heinsohn, and J.D. Miller	50
1996	Field Guidelines for Temporary Ventilation of confined Spaces With an Emphasis on Hotwork by M. Harris, L. Booher, and S. Carter	51
1996	Management of People and Programs in Industrial Hygiene by F.M. Toca and D. Woodhull	52
1996	New Frontiers in Occupational Health and Safety: A Management Systems Approach and the ISO Model ed. by C.F. Redinger and S.P. Levine	53
1996	Occupational Health and Safety Management System: An AIHA Guidance Document (AIHA OHSMS Task Force)	54
1996	Particle Size-Selective Aerosol Sampling in the Workplace: Some Practical Application Issues (AIHA Aerosol Technology Committee)	55
1997	Laboratory Quality Assurance Manual, 2nd ed. (AIHA Sampling and Laboratory Analysis Committee)	56
1997	The Occupational Environment – Its Evaluation and Control ed. by S.R. DiNardi	57
1998	A Strategy for Assessing and Managing Occupational Exposures, 2nd ed. by J.R. Mulhausen and J. Damiano	58
1998	Communicating Risk in a Changing World ed. by T.L. Tinker, M.T. Pavlova, A.R. Gotsch and E.B. Arkin	59
1998	General Concepts for Nonionizing Radiation Protection (AIHA Nonionizing Radiation Committee)	60
1998	Hand-Arm Vibration: A Comprehensive Guide for Occupational Health Professionals, 2nd ed. by P.L. Pelmear and D.E. Wasserman	61
1998	ISO 14000: A Guide to the New Environmental Management Standards	62

1998	Physical Strength Assessment in Ergonomics ed. by S. Gallagher, J.S. Moore, and T.J. Stobbe	63
1998	The Quiet Sickness: A Photographic Chronicle of Hazardous Work in America by E. Dotter	64
1999	Engineering Reference Manual, 2nd ed., (AIHA Engineering Committee) ed. by F.N. Bolton and D.L. Johnson	65
1999	Safety Now! Controlling Chemical Exposures at Hazardous Waste Sites with Real-Time Measurements by C.S.E. Marlowe	66
2000	Current IAQ Practices Worldwide: Proceedings from the 4th IAQ Symposium	67
2000	Glossary of Occupational Hygiene Terms by S.R. DiNardi and W.E. Luttrell	68
2000	Guidelines of Hot Work in Confined Spaces: Recommended Practices for Industrial Hygienists and Safety Professionals by M.H. Finkel	69
2000	Investigations: A Handbook for Prevention Professionals by H.C. Woodcock and J. Seibert	70
2000	Laser Radiation by R.T. Hitchcock and R.J. Rockwell, Jr.	71
2000	Mathematical Models for Estimating Occupational Exposure to Chemicals (AIHA Exposure Assessment Committee) ed. by C.B. Keil	72
2000	Rapid Guide to Hazardous Chemicals in the Workplace, 4th ed. by R.P. Pohanish	73
2000	Risk Assessment Principles for the Industrial Hygienist by M. Jaycock, J. Lynch, and D.I. Nelson	74
2000	The Noise Manual, 5th ed. by E.H. Berger, L.H. Royster, J.D. Royster, D.P. Driscoll and M. Layne	75
2000	User's Guide to 'A Strategy for Assessing and Managing Occupational Exposures, 2nd ed.' (AIHA Exposure Assessment Committee) ed. by T.W. Armstrong and B.D. Silverstein	76
2001	Chemical–Biological Terrorism: Awareness and Response to the Threat	77
2001	Confined Space Entry: An AIHA Protocol Guide, 2nd ed.	78
2001	Hazardous Harvests: Exploring Occupational and Environmental Health and Safety Hazards of U.S. Farmworkers	79
2001	Industrial Hygiene Performance Metrics (AIHA Management Committee)	80
2001	Occupational Asthma: Can This Disease Be Controlled?	81
2001	Report of Microbial Growth Task Force	82
2001	Respiratory Protection: A Manual and Guideline, 3rd ed. (AIHA Respiratory Protection Committee)	83
2001	Synthetic Fibers in the Workplace: Where Less is Healthier	84
2001	Ultraviolet Radiation, 2nd ed.	85
2002	Chemical Safety Handbook: For the Semiconductor/Electronics Industry, 3rd ed. by D.G. Baldwin, M.E. Williams, and P.L. Murphy	86
2002	Ergonomics: From Concept to Practice-Making Ergonomics Work Proceedings from the AIHce 2001 Ergonomics Symposium	87
2002	Ergonomics: Regulations and Standards in the United States, Canada, and Europe	88
2002	Industrial Hygiene Reference & Study Guide by A. Fleeger, D. Lillquist	89
2002	The AIHA 2002 Emergency Response Planning Guidelines and Workplace Environmental Exposure Level Guides Handbook	90
2002	The Noise-Vibration Problem-Solution Workbook by L.H. Royster and J.D. Royster	91
2002	Welding Health and Safety: A Field Guide for OEHS Professionals by M.K. Harris	92
2003	Burton Field Guide for Industrial Hygiene by D.J. Burton	93
2003	Environmental Health and Safety for Hazardous Waste Sites by R.C. Barth, P.D. George and R.H. Hill	94
2003	Essential Resources for Industrial Hygiene: A Compendium of Current Practice Standards and Guidelines (AIHA Practice Standards and Guidelines Committee) ed. by M.K. Harris	95

1984 Symposium on Flow Induced Vibrations, vols 1–6, ed. M.P. Paidoussis *et al.*
1984 Two-Phase Flow and Waterhammer Loads in Vessels, Piping and Structural Systems ed. F.J. Moody and Y.W. Shin
1985 Pressure Vessel and Piping: Design and Analysis – A Decade of Progress ed. C. Sundararajian
1985 Proceeding of the 1985 Pressure Vessels and Piping Conference
PVP 35 Fracture Mechanics, Creep and Fatigue Analysis ed. by C. Becht, S.K. Bhander and B. Tompkins, 1988
PVP 50 Application of Modal Analysis to Extreme Loads ed. by C. Lin, 1988
PVP 53 Current Topics in Piping and Pipe Support Design ed. by E. van Stijgeren, 1981
PVP 54 Computer-Aided Design of Pipe and Pipe Supports ed. by E. van Stijgeren, 1981
PVP 69 Practical Considerations in Piping Analysis ed. by E. van Stijgeren *et al.*, 1982
PVP 103 Fatigue and Fracture Assessment by Analysis and Testing ed. by S.K. Bhandari *et al.,* 1986
PVP 104 Flow-Induced Vibration – 1986 ed. by S.S. Chen, J.C. Simonis and Y.S. Shin
PVP 105 Design and Analysis of Plate and Shells ed. by G.E.O. Widera *et al.,* 1986.
PVP 106 Advances in Impact, Blast, Ballistics, and Dynamic Analysis of Structures ed. by H.H. Chung and D.W. Nicholson, 1986
PVP 107 Pressure Vessels, Piping, and Components – Design and Analysis ed. by W.E. Short *et al.,* 1986
PVP 108 Seismic Engineering for Piping Systems, Tanks, and Power Plant Equipment ed. by T.H. Liu *et al.*
PVP 109 Symposium on ASME Codes and Recent Advances in PVP and Valve Technology Including a Survey of Operations Research Methods in Engineering ed. by J.T. Fong, 1986
PVP 110 High Pressure Technology, Design, Analysis and Safety of High Pressure Equipment ed. by D.P. Kendall, 1986
PVP 111 Materials Property Data: Applications and Access ed. by J.G. Kaufman, 1986
PVP 112 Design and Analysis Methods for Plant life Assessment ed. by T.V. Narayanan and T.J. Kozik, 1986
PVP 114 Properties of High Strength Steels for High-Pressure Containments ed. by E.G. Nisbett, 1986
PVP 115 Nonlinear Analysis and NDE of Composite Material Vessels and Components ed. by D. Hui, J.C. Duke and H. Chung
PVP 116 New Concepts for Verification of Seismic Adequacy of Equipment in Operating Plants, 1986
PVP 120 Design and Analysis of Piping, Pressure Vessels, and Components ed. by W.E. Short *et al.,* 1987 182
PVP 121 Design and Analysis of Composite Material Vessels ed. by D. Hui and T.J. Kozik, 1987
183 PVP 122 Flow-Induced Vibration – 1987 ed. by M.K. Au-Yang and S.S. Chen
PVP 125 High Pressure Engineering and Technology ed. by J.A. Knapp, 1987 184
185 PVP 127 Seismic Engineering – Recent Advances in Design, Analysis, Testing, and Qualification Methods ed. by T.H. Liu and A. Marr
PVP 128 Fluid Structure Vibration and Liquid Sloshing ed. by D.C. Ma and T.C. Su
PVP 129 Advances in Piping Analysis and Life Assessment for Pressure Vessels and Piping ed. by S.J. Chang, R.C. Gwaltney and T.Q. McCawley, 1987
PVP 130 Advances in Design and Analysis in Pressure Vessel Technology ed. by H. Chung *et al.*
PVP 133 Damping ed. by F. Kara *et al.,* 1988
PVP 134 Shock and Wave Propagation ed. by Y.S. Shin and K.S. Kim, 1988
PVP 136 Codes and Standards and Applications for Design and Analysis of Pressure Vessel and Piping Components ed. by R. Seshadri *et al.,* 1988
PVP 137 Dynamics and Seismic Issues in Primary and Secondary Systems ed. by K. Karim- Panahi and A. Der Kiureghian, 1988
PVP 138 Life Extension and Assessment: Nuclear and Fossil Power-Plant Components ed. by C.E. Jaske *et al.,* 1988
PVP 139 Design and Analysis of Piping, Pressure Vessels, and Components – 1988 ed. by Q.N. Truong *et al.*
PVP 140 Unsteady Flows and Design Considerations in Vessel and Piping Systems ed. by Y.W. Shin and F.J. Moody, 1988
PVP 141 Elastic–Plastic Failure Modelling of Structures with Applications ed. by D. Hui and T.J. Kozik, 1988
PVP 143 Advanced Topics in Finite Element Analysis ed. by J.F. Cory and J.L. Gordon, 1988
PVP 144 Seismic Engineering – 1988 ed. by T.H. Liu *et al.*
PVP 145 Sloshing, Vibration, and Seismic Response of Fluid–Structure Systems ed. by D.C. Ma and S.S. Chen, 1988
PVP 147 Seismic, Shock and Vibration Isolation – 1988 ed. by H.H. Chung and N. Mostaghei
PVP 148 High Pressure Technology – Material Design, Stress Analysis, and Applications ed. by A.K. Khare, 1988
PVP 149 Advances in Dynamic Analysis of Plates and Shells ed. by H.H. Chung, 1988

PVP 151	Understanding Variability in Creep and Rupture Behaviour ed. by M. Prager and J.D. Parker, 1988
PVP 154	Flow-Induced Vibration – 1989 ed. by M.K. Au-Yang *et al.*
PVP 155	Application of Modal Analysis to Seismic and Dynamic Loads ed. by C.W. Lin and T.H. Liu, 1989
PVP 157	Sloshing and Fluid Structure Vibration – 1989 ed. by D.C. Ma *et al.*
PVP 158	Advances in Bolted Joint Technology ed. by K.H. Hsu *et al.,* 1989
PVP 161	Codes and Standards and Applications for Design and Analysis of Pressure Vessel and Piping Components – 1989
PVP 162	Earthquake Behaviour of Buried Pipelines, Storage, Telecommunications and Transportation Facilities ed. by T. Ariman *et al.,* 1989
PVP 163	Structural Design for Elevated Temperatures – Creep, Ratchet, Fatigue, and Fracture ed. by C. Becht, 1989
PVP 165	High Pressure Engineering and Technology – 1989 ed. by R.G. Fasiczka
PVP 166 and 167	Advances in Fracture and Fatigue for the 1990s, vols I–II, 1989
PVP 168	Metallic Bellows and Expansion Joints ed. by C. Becht and B. Jetter, 1989
PVP 169	Design and Analysis of Piping and Components – 1989 ed. by Q.N. Truong *et al.*
PVP 171	Life Assessment and Life Extension of Power Plant Components –1989 ed. by T.V. Narayanan *et al.*
PVP 173	Weld Residual Stresses and Plastic Deformation ed. by E. Rybicki and M. Shiratori, 1989
PVP 175	Design and Analysis of Pressure Vessels, and Components – 1989 ed. by G. Brooks
PVP 178	Dynamics of Plates and Shells – 1989 ed. by H. Chung *et al.*
PVP 180	Pipeline Dynamics and Valves – 1989 ed. by M.A.L. Aggarwal, L.I. Ezekoy and M.A. Saleem
PVP 181	Seismic, Shock and Vibration Isolation – 1989 ed. by H. Chung and T. Fujita
PVP 182	Seismic Engineering – 1990 ed. by T.H. Hiu and F. Kara
PVP 183	Recent Developments in Buckling of Structures – 1989 ed. by D. Hui, V. Birman and D. Bushnell
PVP 186	Codes and Standards and Applications for Design and Analysis of Pressure Vessel and Piping Components –1990 ed. by R.F. Samataro *et al.,* 1990
PVP 188	Design and Analysis of Piping and Components – 1990 – Including Valve Testing and Applications ed. by Q.N. Truong, W.E. Short and L.I. Ezekoye, 1990
PVP 189	Flow-Induced Vibration –1990 ed. by S.S. Chen, K. Fujita and M.K. Au-Yang
PVP 191	Flow-Induced Vibration and Sloshing – 1990 ed. by D.C. Ma, J. Tani and S.S. Chen
PVP 192	High Pressure Technology, Fracture Mechanics and Service Experience in Operating Power Plants ed. by S.Y. Zamrik and E.H. Perez
PVP 193	Damage Assessment, Reliability, and Life Prediction of Power Plant Components ed. by R.N. Pangborn *et al.,* 1990
PVP 194	Analysis of Pressure Vessel and Heat Exchanger Components ed. by W.E. Short and G.N. Brooks, 1990
PVP 195	Fatigue, Degradation, and Fracture – 1990 ed. by W.H. Bamford *et al.*
PVP 196	Composite Materials for PVP Applications ed. by D. Hui and T.J. Kozik, 1990
PVP 197	Seismic Engineering – 1990 ed. by T.H. Liu *et al.*
PVP 198	Advances in Dynamics of Piping and Structural Components ed. by H.H. Chung *et al.,* 1990
PVP 200	Seismic, Shock and Vibration Isolation – 1990 ed. by H.H. Chung
PVP 201	New Alloys for Pressure Vessels and Piping ed. by M. Prager and C. Cantzler, 1990

Report Investigations

RI 2491	Hydrogen sulphide as an industrial poison by R.R. Sayers, C.W. Mitchell and W.P. Yant, 1923
RI 3274	Accuracy of manometry of explosions by H.F. Coward and M.D. Hersey, 1935
RI 3278	Limits of inflammability of diethyl ether and ethylene in air and oxygen by G.W. Jones *et al.,* 1935
RI 3722	Inflammability and explosibility of metal powders by I. Hartmann, J. Nagy and H.R. Brown, 1943
RI 3731	Inflammability of powders used in the metals RI 5671 industry by I. Hartmann and J. Nagy, 1944
RI 3751	Inflammability and explosibility of powders used in the plastics industry by I. Hartmann R.I. 5707 and J. Nagy, 1944
RI 3826	Effect of pressure on the explosibility of acetylene–water vapor, acetylene–air and acethyphen; ylene–hydrocarbon mixtures by G.W. Jones, R.F. Kennedy, I. Spolan and W.J. Huff, 1945

RI 3867	Report on the investigation of the fire at the storage and regasification plant of the East Ohio Gas Co., Cleveland, Ohio, October 20, 1944 by M.A. Elliott, C.W. Subel, F.N. Brown, R.T. Artz and L.B. Berger, 1946
RI 3924	Effect of relief vents on reduction of pressures developed by dust explosions by I. Hartmann and J. Nagy, 1946
RI 4191	Investigation of February 10, 1973 explosion, Staten Island liquefied gas storage tank by M.G. Zabetakis and D.S. Burgess, 1973
RI 4245	Explosions of ammonium nitrate fertiliser on board the SS *Grandcamp* and the SS *Highflyer* at Texas City, Tex., April 16–17, 1947 by G.M. Kintz, G.W. Jones and C.B.Carpenter, 1948
RI 4636	Pressure relieving capacities of diaphragms and other devices for venting dust explosions by J. Nagy, J.E. Zeilinger and I.Hartmann, 1950
RI 4725	Recent studies of the explosibility of corn starch by I. Hartmann, A.R. Cooper and M. Jacobsen, 1950
RI 4835	Explosive characteristics of titanium, zirconium,thorium, uranium and their hydrides by I. Hartmann, J. Nagy and M.Jacobsen, 1951
RI 4904	A study to determine factors causing pressure piling in testing explosion-proof enclosures by E.J. Gleim and J.F. March, 1952 RI 6516
RI 5052	Laboratory explosibility of American coals by Hartmann, M. Jacobsen and Williams, 1954
RI 5198	Fire and explosion hazards in thermal coal-drying plants by H.R. Brown, C.J. Dalzell, I. Hartmann, G.J.R. Toothman and C.H. Schwartz, 1956
RI 5225	Fundamental flashback, blowoff and yellow-tip limits of fuel gas–air mixtures by J. Grummer, M.E. Harris and V.R. Rowe, 1956
RI 5457	Communication of flame through cylindrical channels by H.G. Wolfhard and A.E. Bruszak, 1959
RI 5461	Recent developments in spark ignition by E.I. Litchfield and M.V. Blanc, *c.*1959
RI 5476	Investigations on the explosibility of ammonium nitrate by J. Burns *et al.,* 1953
RI 5610	Flammability limits of methane and ethane in chlorine at ambient and elevated temperatures and pressures by A. Bartkowiak and M.G. Zabetakis, 1960
RI 5624	Laboratory equipment and test procedures for evaluating explosibility of dusts by H.G. Dorsett *et al.,* 1960
RI 5645	Explosion at dephlegmator at Cities Service Oil Company Refinery, Ponca City, Oklahoma, 1959 by M.G. Zabetakis, 1960
RI 5671	Minimum ignition energy concept and its application to safety engineering by E.L. Litchfield, 1960
RI 5707	Research on the hazards associated with the production and handling of liquid hydrogen by M.G. Zabetakis and D.S. Burgess, 1961
RI 5753	Explosibility of agricultural dusts by M. Jacobsen, J. Nagy, A.R. Cooper and F.J. Ball, 1961
RI 5815	Explosibility of coal dust in an atmosphere containing a low percentage of methane by J. Nagy and Portman, 1961
RI 5877	Flammability and detonability studies of hydrogen peroxide systems containing organic substances by J.M. Kuchta, G.H. Martindill, M.G. Zabetakis and G.H. Damon, 1961
RI 5971	Explosibility of dusts used in the plastics industry by M. Jacobsen, J. Nagy and A.R. Cooper, 1962
RI 5992	Flammability and autoignition of hydrocarbon fuels under static and dynamic conditions by J.M. Kuchta, S. Lambiris and M.G. Zabetakis, 1962
RI 6099	Fire and explosion hazards associated with liquefied natural gas by D.S. Burgess and M.G. Zabetakis, 1962
RI 6112	Autoignition of lubricants at elevated pressures by M.G. Zabetakis, G.S. Scott and R.E. Kennedy, 1962
RI 6293	The ignition of combustible mixtures by laminar jets of hot gases by M. Vanpee and A.F. Bruszak, 1963
RI 6309	Hazards in using liquid hydrogen in bubble chambers by M.G. Zabetakis, A.L. Furno and H.E. Perlee, 1963
RI 6369	Ignition of coal dust–methane–air mixtures by hot turbulent gas jets by J.M. Singer, 1964
RI 6516	Explosibility of metal powders by M. Jacobsen, A.R. Cooper and J. Nagy, 1964
RI 6543	Preventing ignition of dust dispersions by inerting by J. Nagy, H.G. Dorsett and M. Jacobson, 1964
RI 6561	Pressure development in laboratory dust explosions by J. Nagy, A.R. Cooper and J.M. Stupar, 1964
RI 6597	Explosibility of carbonaceous dusts by J. Nagy, H.G. Dorsett and A.R. Cooper, 1965
RI 6651	Some fundamental aspects of dust flames by H.M. Cassel, 1964
RI 6654	Autoignition of hydrocarbon jet fuel by J.M. Kuchta, A. Bartkowiak and M.G. Zabetakis, 1965
RI 6659	Flammability characteristics of ethylene by G.S. Scott, R.E. Kennedy, I. Spolan and M.G. Zabetakis, 1965
RI 6747	Sympathetic detonation of ammonium nitrate and ammonium nitrate-fuel oil by R.W. van Dolah *et al.,* 1966
RI 6773	Explosibility of ammonium nitrate under fire exposure by R.W. van Dolah *et al.*
RI 6811	Thermal phenomena during ignition of a heated dust explosion by J. Nagy and D.J. Surincik, 1966
RI 6840	Detonation initiation in alkane–oxygen mixtures by E.L. Litchfield and M.H. Hay, 1966
RI 6851	Explosibility of metal powders by M. Jacobsen, M. Cooper and J. Nagy, 1965

RI 6903	Further studies on sympathetic detonation by R.W. van Dolah, 1966
RI 6931	Equivalence and lower ignition limits of coal dust and methane mixtures by J.M. Singer, E.B. Cook and J. Grumer, 1967
RI 7061	Initiation of spherical detonation in acetylene–oxygen mixtures by E.L. Litchfield and M.H. Hay, 1967
RI 7103	Limits of flame propagation of coal dust – methane–air mixtures by J.M. Singer, A.E. Bruzsak and J. Grumer, 1968
RI 7132	Dust explosibility of chemicals, drugs, dyes and pesticides by H.G. Dorsett and J. Nagy, 1968
RI 7196	Large-scale studies of gas detonations by D.S. Burgess, J.N. Murphy, N.E. Hanna and R.W. van Dolah, 1968
RI 7208	Explosibility of miscellaneous dusts by J. Nagy, A.R. Cooper and H.G. Dorsett, 1968
RI 7279	Explosion development in a spherical vessel by J. Nagy, J.W. Conn and H.C. Verakis, 1969
RI 7448	Hazards associated with the spillage of liquefied natural gas on water by D.S. Burgess, J.N. Murphy and M.G. Zabetakis, 1970
RI 7457	Hydrogen flare stack diffusion phenomena: low and high flow instabilities, burning rates, dilution limits, temperatures and wind effects by J. Grumer *et al.,* 1970
RI 7507	Explosion development in closed vessels by J. Nagy, B.C. Seller, J.W. Conn and H.C. Verakis, 1971
RI 7552	Inhibition of coal–dust air flames by J. Grumer, 1971
RI 7752	Detonation of a flammable cloud following a propane pipeline break: the December 9, 1970, explosion in Port Hudson, Mo. by D.S. Burgess and M.G. Zabetakis, 1973
RI 7839	Constant volume flame propagation by H.E. Perlee, F.N. Fuller and C.H. Saul, 1974
RI 8127	The theory of flammability limits. Natural convection by M. Hertzberg, 1976
RI 8176	Flame and pressure development of large-scale CH_4–air–N_2 explosions. Buoyancy effects and venting requirements by M.J. Sapko, A.L. Furno and J.M. Kuchta, 1976
RI 8187	Compressor and related explosion by H.E. Perlee and M.G. Zabetakis, *c.*1963
RI 8201	Ignition in mixtures of coal–dust, air and methane from abrasive impacts of hard materials with pneumatic pipeline steel by J.S. Kelley and B.L. Forkner, 1976
RI 8360	The flammability of coal dust–air mixtures by M. Hertzberg, K.L. Cashdollar and J.J. Opferman, 1979

Technical Papers

Tech. Pap. 475	Ignition of natural gas–air mixtures by heated surfaces by P.G. Guest, 1930
Tech. Pap. 553	Protection of equipment containing explosive acetone–air mixtures by the use of diaphragms by G.W. Jones, E.S. Harris and B.B. Beattie, 1933

PMSRC series

PMSRC 4177	Hazards of spillage of LNG onto water by D.S. Burgess, J. Biordi and J.N. Murphy, 1972

S series

S 4105	Hazards of LNG spillage in marine transportation by D.S. Burgess, J.N. Murphy and M.G. Zabetakis, 1970

CONCAWE

(The Hague, The Netherlands)

General Interest Reports (Yellow covers)

2/70	Corrosion: protection and inspection
3/70	Prevention of water pollution from refineries
9/70	Pollution of permeable strata by oil components
9/71	Migration of oil in soil
4/72	Surveying air pollution around oil refineries
5/73	Current methods of routine testing and leak detection in operating oil pipelines
4/74	Inland oil spill clean-up manual
2/75	Incineration of refinery wastes
3/75	Sampling of refinery liquid effluents
8/75	The identification and measurement of refinery odours
2/76	Determination of sound power levels of industrial equipment, particularly oil industry plant
6/76	Effluents and emissions from European refineries
2/77	Published regulatory guidelines of environmental concern to the oil industry in Western Europe
3/77	Test method for the measurement of noise emitted by furnaces for use in the petroleum and petrochemical industries
8/77	Measurement of vibrations complementary to sound measurement
9/77	Spillages from oil industry cross-country pipelines in Western Europe. Statistical summary of reported incidents
3/79	Protection of groundwater from oil pollution
5/79	The environmental impact of refinery effluents
9/80	Disposal techniques for spilt oil
4/81	The propagation of noise from petroleum and petrochemical complexes to neighbouring communities
7/81	Revised inland oil spill clean-up manual
9/81	A field guide to coastal oil spill control and clean-up techniques
8/82	Ecological monitoring of aqueous effluents from petroleum refineries
10/82	Methodologies for hazard analysis and risk assessment in the petroleum refining and storage industry
7/83	Guidelines for recording industrial hygiene data
10/83	A field guide to inland oil spill clean-up techniques
4/85	Investigations into the relationships between the chemical composition of mineral oils and their ability to cause skin cancer in mice
5/85	Strategies for the assessment of the biological impacts of large coastal oil spills – European coasts
7/85	Workplace noise and hearing conservation
2/86	Volatile organic compound emissions: an inventory for Western Europe
3/86	The health experience of workers in the petroleum manufacturing and distribution industry
2/87	Review of European oil industry benzene exposure data
4/87	A survey of exposures to gasoline vapour
7/87	Health aspects of toluene and xylene exposures associated with motor gasoline

11/87	Emergency planning guidance notes – Selecting the incident scenarios for off-site emergency planning/Responsibilities of petroleum industry and regulatory authorities in off-site emergency planning/Information to the public
2/88	A field guide to the application of dispersants to oil spills
5/88	Emergency planning guidance notes – Content of emergency plans/Planning for mutual aid
6/88	Emergency planning guidance notes – Refinery emergency planning
2/89	Emergency planning guidance notes – Training, exercises and rehearsal of emergency plans/Communications during emergencies
4/89	Managing safety
7/89	Emergency planning guidance note – Marketing installation emergency planning
5/90	A field guide on reduction and disposal of waste from oil refineries and marketing installations
4/92	Performance of oil industry cross-country pipelines in Western Europe – statistical summary of reported spillages 1991
7/94	Review of European oil industry benzene exposure data (1986–1992)
1/95	Oil refinery waste disposal methods, quantities and costs – 1993 survey
5/96	Collection and disposal of used lubricating oil
2/97	European oil industry guideline for risk-based assessment of contaminated sites
3/97	Task risk assessment
1/98	Methods of prevention, detection and control of spillages in European oil pipelines
4/98	European downstream oil industry safety performance – statistical summary of reported incidents – 1997 and overview 1993 to 1997
7/98	The SEVESO II directive and the oil industry
8/98	Trends in oil discharged with aqueous effluents from oil refineries in Europe – 1997 survey
1/99	European downstream oil industry safety performance – statistical summary of reported incidents – 1998
2/99	Environmental exposure to benzene
1/00	European downstream oil industry safety performance – statistical summary of reported incidents – 1999
2/00	A review of European gasoline exposure data for the period 1993 – 1998
3/01	European downstream oil industry safety performance – statistical summary of reported incidents – 2000
4/01	Performance of cross-country oil pipelines in Western Europe statistical summary of reported spillages – 2000
1/02	Western European cross-country oil pipelines – 30-year performance statistics
7/02	Assessment of personal inhalation exposure to bitumen fume guidance for monitoring benzene-soluble inhalable particulate matter
8/02	Method for monitoring exposure to gasoline vapour in air – revision 2002
9/02	A survey of European gasoline exposures for the period 1999–2001
2/03	Catalogue of CONCAWE reports

Special Interest Reports (White covers)

84/52	Recommended practice for investigating and dealing with
84/54	Petroleum hydrocarbons: their absorption through and effect on skin
84/55	The study of noise from steel pipes
84/64	Experimental verification of the ISVR pipe noise model
86/69	Health aspects of worker exposures to oil mists
87/52	Cost-effectiveness of hydrocarbon emission controls in refineries from crude oil receipt to product dispatch
87/57	Review of strategies for the evaluation of employee exposures to substances hazardous to health
87/59	The prediction of noise radiating from pipe systems – an engineering procedure for plant design
88/56	Quantified risk assessment
89/53	Health risks from working in petroleum refining and from gasoline – a critique and recommendations in response to IARC monograph volume 45
89/55	Review of EC health and safety directives
90/53	An assessment of occupational exposure to noise in Western European oil refineries
91/53	The role of epidemiology in the health assessment of petroleum industry employees
91/55	The European Community legislative process
92/55	The EC Safety Data Sheet Directive
93/52	Industrial hygiene seminar
95/60	Determination of air quality standards bands for ozone
95/62	Air quality standard for particulate matter
96/54	Development of a health surveillance programme for workers in the downstream petroleum industry
96/63	Scientific basis for an air quality standard on benzene
97/51	Scientific basis for an air quality standard for carbon monoxide complaints about noise
00/52	Management of occupational health risks during refinery turnarounds
01/52	A noise exposure threshold value for hearing conservation
01/56	An assessment of occupational exposure to noise in the European oil industry (1989–1999)
02/57	Catalogue of special interest reports

PE 6	The choice of fixed fire extinguishing systems, 1990
PE 7	Hose reels, 1988
PE 8	Hydrant systems, 1989
PE 9	Automatic sprinklers: an introduction, 1989
PE 10	Automatic sprinklers: components of a system (withdrawn)
PE 11	Automatic sprinklers: design and installation, 1989
PE 12	Automatic sprinklers: care and maintenance, 1989
PE 13	Automatic sprinklers: safety during sprinkler shutdown, 1985
PE 17	Automatic fire ventilation systems, 1989

Security precautions

SEC 1	Security equipment and systems, 1990
SEC 2	Site layout, 1990
SEC 3	Fences, gates and barriers, 1990
SEC 4	External security lighting, 1985
SEC 5	External closed circuit television systems, 1990
SEC 6	Doors, 1985
SEC 7	Windows and rooflights, 1985
SEC 8	Access control, 1991
SEC 9	Locks (withdrawn)
SEC 10	Hardware for fire and escape doors, 1991

Arson

AR 1	Management guide to fire
AR 2	Prevention and control of arson in warehouse and storage buildings, 1992
AR 4	Incendiary devices: information and guidance, 1990
AR 5	Investigation of vehicle fires

Vol. 6

Building and fire

Design guides

FPDG1	Fire prevention design guide: fire and the law, 1989
FPDG2	Fire prevention design guide: site requirements – space separation (withdrawn)
FPDG3	Fire prevention design guide: control of fire and smoke within a building, 1990
FPDG4	Fire prevention design guide: planning means of escape
FPDG5	Fire prevention design guide: fire fighting facilities for the fire brigade (withdrawn)
FPDG6	Fire prevention design guide: equipment for detection and warning of fire and fighting fire, 1991
FPDG7	Fire prevention design guide: fire hazard assessment, 1990
FPDG8	Fire prevention design guide: fire insurance (withdrawn)
FPDG9	Fire prevention design guide: building services, 1990
FPDG10	Fire prevention design guide: cavities and voids in building construction
FPDG11	Fire prevention design guide: suspended ceilings (withdrawn)
FPDG12	Fire prevention design guide: construction of roofs
FPDG13	Fire prevention design guide: flame retardant treatment for wood and its derivatives, 1990
FPDG14	Fire prevention design guide: fire doors and shutters
FPDG15	Fire prevention design guide: upgrading factory buildings to control fire spread
FPDG16	Air conditioning and ventilating systems, 1989

Building products

Fire properties of building products, including

B 15	Fire resistant glazing – wired glass, 1984
B 18	Fire resistant glazing – laminated wired glass, 1985

Fire Safety Sheets

S3		Waste incinerators
S4	1973	Oil-soaked floors
S5	1974	Safety containers for flammable liquids
S6	1974	Fire points
S7	1974	Protection of records, plans and documents

Fire Research Station

(London: HM Stationery Office)

Fire Notes

F1 Fire Resistance of Floors and Ceilings by G.I. Bird, 1961
F3 Roofs and Fire
F4 Tests on Roof Construction Subjected to External Fire
F5 Fire Venting in Single-Storey Buildings by G.J. Langdon-Thomas and P.L Hinkley, *c.*1965
F6 Fire Resistance of Brick and Block Walls by H.L. Malhotra
F8 Fire and the External Wall by G.J. Langdon-Thomas and M. Law, 1966

Fire Research Technical Papers

5 Heat Radiation from Fires and Building Separation by M. Law, 1963
10 Design of Roof Venting Systems for Single-Storey Buildings by P.M. Thomas and P.L. Hinkley, *c.*1964
15 The Temperature Attained by Steel in Building Fires by E.G. Butcher, T.B. Chitty and L.A. Ashton, 1966
21 Explosibility Tests for Industrial Dusts, 2nd ed., by M.M. Raftery, 1975

Fire Research Notes

298 The venting of explosions in duct systems. Part II, The venting of explosions in pentane–air mixture in a duct 6 ft long × 6 in. diameter by D.J. Rasbash and Z.W. Rogowksi, 1956
516 On the size and orientation of buoyant diffusion flames and the effect of wind by P.M. Thomas, R.W. Pickard and H.G.H. Wraight, 1963
600 Fire spread in wood cribs. Pt III, The effect of wind by P.M. Thomas
609 Fire protection of liquid fuel storage by P.M. Thomas and M. Law, 1965
658 The protection of equipment with flame arresters: 2, Effect of contents, and use of improved arresters by K.N. Palmer and Z.W. Rogowski, 1967
759 The relief of gas and vapour explosions in domestic structures by D.J. Rasbash, 1969
760 Use of mechanical ventilation to reduce explosion hazards in high flats by K.N. Palmer, 1969
810 The behaviour of automatic fire detection systems by J.F. Fry and C. Eveleigh, 1970
820 Gas explosions in dwellings, 1969: material damage and injuries by E.D. Chambers
830 Dust explosion venting – a reassessment of the data by K.N. Palmer
847 Gas explosions in multiple compartments by D.J.Rasbash, K.N. Palmer, Z.W. Rogowksi and S.A. Ames, 1971
899 Considerations of the fire size to operate and the water distribution from automatic sprinklers by M.J. O'Doghtery and P. Nash, 1971
909 Some notes on the mathematical analysis of safety by R. Baldin, 1972
910 Extreme value theory and fire losses by G. Ramachandran, 1972
913 The thermal decomposition behaviour of some commercially available flexible polyurethane foams by W.D. Woolley, A.I. Wadley and P. Field, 1972
914 Experiments with sprinklers in high-racked storages. 2, Extinction with face-mounted sprinklers by P. Nash, N.W. Bridge and R.A. Young, 1972
916 Experiments with sprinklers in high-racked storages. 1, Extinction with centrally mounted sprinklers by P. Nash, N.W. Bridge and R.A. Young, 1972
920 Fires in oil refineries and outdoor chemical plant in 1969 by S.E. Chandler, 1972
921 The projection of flames from burning buildings by P.M. Thomas and M. Law, 1972
925 Compatibility of fluorochemical and protein fire-fighting foams by T.B. Chitty, D.J. Griffiths and J.G. Corrie, 1972
929 An application of the theory of extreme values for estimating the delay in the discovery of a fire by G. Ramachandran, 1972
931 Performance of metal foam as a flame arrester when fitted to gas explosion relief vents by Z.W. Rogowski and S.A. Ames, 1972
932 Failure rates of automatic fire detection and alarm systems by E.D. Chambers, 1972
937 The safety of hot self-heating materials in cool surroundings – a method of analysis by P.M. Thomas, 1972
938 The performance of some portable gas detectors with aviation fuel vapours at elevated temperatures. Pt 1 – Tests with n-hexane, 'AVTAG' and 'CIVGAS' vapours by P.J. Fardell, 1972
942 Dust explosions in a large cyclone plant by P.S. Tonkin and C.F.J. Berlemont, 1972
943 Extreme value theory and fire resistance by G. Ramachandran, 1972
944 The rapid extinction of fire in high-racked storages by P. Nash, N.W. Bridge and R.A. Young, 1972
945 Flashback through crimped ribbon arresters by Z.W. Rogowski and S.A. Ames, 1972
947 The production of free toluene diisocyanate from the thermal and thermal-oxidative decomposition of flexible polyurethane foams by W.D. Woolley and A.I. Wadley, 1972
950 A method of evaluating human life for economic purposes by S.K. Melinek, 1972
951 Studies of the thermal decomposition of flexible polyurethane foams by air by W.D. Woolley, A.I. Wadley and P. Field, 1972

953 The behaviour of people in fires by P.G. Wood, 1972
957 The performance of some portable gas detectors with aviation fuel vapours at elevated temperatures. Pt 2 – Tests with 'AVCAT', 'KERO B' and 'AVTUR' vapours by P.J. Fardell, 1973
959 Preliminary experiments on the use of water additives for friction reduction in fire hoses by P.F. Thorne and K. Jordan, 1973
961 Dust explosion venting – consideration of further data by K.N. Palmer, 1973
963 Passive and active fire protection – the optimum combination by R. Baldwin and P.M. Thomas, 1973
964 Evaluation of road tanker dip tubes as flame barriers by Z.W. Rogowski and C.P. Finch, 1973
966 The production of oxides of carbon from the thermal and thermal-oxidative decomposition of flexible polyurethane foams by W.D. Woolley and A.I. Wadley, 1973
973 The effect of explosion pressure relief on the maximum experimental safe gap of propane–air and ethylene–air mixtures by Z.W. Rogowski and S.A Ames, 1973
974 Explosion protection of equipment with flame arresters – specification of methods of test and construction, 1973
978 Loss of life expectancy due to fires by S.K. Melinek, 1973
980 Storage properties of four foam liquids (Final report) by S.P. Benson, D.J. Griffiths, D.M. Tucker and J.G. Corrie, 1973
981 The risk of dying by fire by M.A. North, 1973
982 The economics of accident prevention – explosions by S.K.D. Coward, 1973
984 Gas explosions in buildings. Pt 1, Experimental explosion chamber by P.S. Tonkin and C.F.J. Berlemont, 1974
985 Gas explosions in buildings. Pt 2, The measurement of gas explosion pressure by S.A. Ames, 1974
990 Effect of pressure relief on the maximum experimental safe gaps of hydrogen/air mixtures by Z.W. Rogowski and C.P. Finch, 1973
991 Factors affecting fire loss – multiple regression model with extreme values by G. Ramachandran, 1973
992 Dust explosion hazards in pneumatic transport by K.N. Palmer, 1973
993 The compatibility of fluorochemical and fluoroprotein foams by S.P. Benson, D.J. Griffiths and J.G. Corrie, 1973
1003 Experimental appraisal of an American sprinkler system for the protection of goods in high-racked storage by N.W. Bridge and R.A. Young, 1974
1007 A laboratory fire test for foam liquids by S.P. Benson, P.R. Bevan and J.G. Corrie, 1974
1011 Some statistics of fire in road vehicles by N.A. North, 1974
1018 The transmission of explosion of flammable gas/air mixtures through a flame gap on a vented vessel by Z.W. Rogowski, 1974
1019 Pressures produced by gas explosion in a vented compartment by R.N. Butlin and P.S. Tonkin, 1974
1022 Flash points of mixtures of flammable and nonflammable liquids by P.F. Thorne
1025 Casualties attributed to toxic gas and smoke at fires – a survey of statistics by P.C. Bowes, 1975
1026 A review of information on experiments concerning the venting of gas explosions in buildings by R.N. Butlin, 1975
1028 Maximum permissible oxygen concentrations to prevent dust explosions in a large scale vertical explosion tube by P.S. Tonkin, 1975
1029 The early stages of fire growth in a compartment: a co-operative research programme of the CIB (Commission W14). First phase by A.J.M. Heselden and S.J. Melinek, 1975
1037 Performance of a two element crimped ribbon flame arrester by Z.W. Rogowski and A. Pitt
1044 The evaluation of an improved method of gas-freeing an aviation fuel storage tank by P.J. Fardell and B.W. Houghton, 1975
1048 The inhalation toxicity of polyvinyl chloride pyrolysis products by P.C. Bowes, J.A.C. Edginton and R.D. Lynch
1054 Estimation of maximum explosion pressure from damage to surrounding buildings. Explosion at Mersey House, Bootle, 28 August 1975 by R.N. Butlin, 1976
1063 Test performance of automatic fire alarm equipment by G. Cowie, 1977
1068 The protection of high-racked storages by commercial zoned sprinkler systems by S.P. Rogers and R.A. Young, 1977
1073 The toxicity of halon extinguishing agents by P.F. Thorne, 1977
1074 Use of a nitrogen filled high expansion foam to protect a 500 tonne fuel tank by A.A. Briggs, 1977
1078 The construction of flammability diagrams from flash-point measurements by P.F. Thorne and A.A. Briggs, 1978

(series discontinued in 1978)

Medical

MS 4	Organic dust surveys, 1977
MS 5	Lung function, 1977 (not in current list)
MS 7	Colour vision, rev., 1987
MS 8	Isocyanates: medical surveillance, 1983 (not in current list)
MS 12	Mercury: medical surveillance, 1978
MS 13	Asbestos,rev., 1988
MS 15	Welding, 1978
MS 18	Health surveillance by routine procedures (not in current list)
MS 24	Health surveillance of occupational skin disease, 1991
MS 25	Medical aspects of occupational asthma, 1991

Plant and machinery

PM 1	Guarding of portable pipe-threading machines,1984
PM 3	Erection and dismantling of tower cranes, 1976 (not in current list)

PM 5	Automatically controlled steam and hot water boilers, rev., 1989
PM 9	Access to tower cranes, 1979 (not in current list)
PM 13	Zinc embrittlement of austenitic stainless steel, 1977
PM 14	Safety in the use of cartridge operated tools, 1978 (not in current list)
PM 15	Safety in the use of timber pallets, 1993
PM 16	Eyebolts, 1978
PM 19	Use of lasers for display purposes, 1980
PM 21	Safety in use of woodworking machines, 1981
PM 22	Training advice on the use of abrasive wheels, 1983
PM 23	Photo-electric safety systems, 1981
PM 24	Safety at rack and pinion hoists, 1981
PM 27	Construction hoists, 1981 (not in current list)
PM 28	Working platforms on forklift trucks, 1981
PM 29	Electrical hazards from steam/water pressure cleaners, rev., 1988
PM 30	Suspended access equipment, 1983
PM 32	Safe use of portable electrical apparatus, 1990
PM 38	Selection and use of electric handlamps, 1992
PM 41	Application of photo-electric safety systems to machinery, 1984
PM 53	Emergency private generation: electrical safety, 1985
PM 54	Lifting gear standards, 1985
PM 56	Noise from pneumatic systems, 1985
PM 58	Diesel engined lift trucks in hazardous areas, 1986
PM 60	Steam boiler blowdown systems, 1987
PM 64	Electrical safety in arc welding, 1986
PM 65	Worker protection at crocodile (alligator) shears, 1986
PM 73	Safety at autoclaves, 1990
PM 75	Glass reinforced plastic vessels and tanks: advice to users, 1991

Guidance Booklets

HS(G) 3	Highly flammable materials on construction sites, 1978
HS(G) 5	Hot work: welding and cutting on plant containing flammable materials, 1979
HS(G) 6	Safety in working with lift trucks, 1979
HS(G) 7	Container terminals: safe working practice, 1980
HS(G) 11	Flame arresters and explosion reliefs, 1980
HS(G) 12	Offshore construction: health, safety and welfare, 1980
HS(G) 13	Electrical testing: safety in electrical testing, 1980 (not in current list)
HS(G) 15	Storage of liquefied petroleum gas at factories, 1981 (not in current list)
HS(G) 16	Evaporating and other ovens, 1981
HS(G) 17	Safety in the use of abrasive wheels, 1984
HS(G) 19	Safety in working with power operated work platforms, 1982
HS(G) 20	Guidelines for occupational health services, 1982
HS(G) 22	Electrical apparatus for use in potentially explosive atmospheres, 1984
HS(G) 25	Control of Industrial Major Accident Hazards Regulations 1984 (CIMAH): further guidance on emergency plans, 1985
HS(G) 26	Transport of dangerous substances in tank containers, 1986
HS(G) 27	Substances for use to work: provision of information, 1985
HS(G) 28	Safety advice for bulk chlorine installations, 1986
HS(G) 30	Storage of anhydrous ammonia under pressure in the United Kingdom: spherical and cylindrical vessels
HS(G) 34	Storage of LPG at fixed installations,1987
HS(G) 37	Introduction to local exhaust ventilation, 1987
HS(G) 38	Lighting at work, 1987
HS(G) 39	Compressed air safety, 1990
HS(G) 40	Chlorine from drums and cylinders, 1987
HS(G) 43	Industrial robot safety, 1988
HS(G) 48	Human factors in industrial safety, 1989
HS(G) 51	The storage of flammable liquids in containers, 1990
HS(G) 52	The storage of flammable liquids in fixed tanks (exceeding 10,000 m^3 total capacity), 1991
HS(G) 53	Respiratory protective equipment: a practical guide for users, 1990
HS(G) 54	The maintenance, examination and testing of local exhaust ventilation, 1990
HS(G) 56	Noise at work. Noise assessment, information and control, 1990
HS(G) 61	Surveillance of people exposed to health risk at work, 1990
HS(G) 64	Assessment of fire hazards from solid materials and the precautions required for their safe storage and use, 1991
HS(G) 65	Successful health and safety management, 1991
HS(G) 71	Storage of packed dangerous substances, 1992
HS(G) 78	Container packing, 1992
HS(G) 96	The costs of accidents at work, 1993

Regulations Booklets

HS(R) 1	Packaging and Labelling of Dangerous Substances – Regulations and Guidance Notes, 1978
HS(R) 3	Guide to tanker marking regulations, 1979
HS(R) 6	Guide to the HSW Act, 1983
HS(R) 7	Guide to the Safety Signs Regulations 1980, 1981
HS(R) 8	Guide to the Diving Operations at Work Regulations 1981, 1981
HS(R) 11	First-aid at work, 1981
HS(R) 13	Guide to the Dangerous Substances (Conveyance by Road in Road Tankers) Regulations 1981, 1981
HS(R) 14	Guide to the Notification of New Substances Regulations 1982, 1982
HS(R) 15	Administrative guidance on the implementation of the European Community 'Explosive Atmospheres' Directive (76/117/EEC and 79/196/EEC), 1983
HS(R) 16	Guide to the Notification of Installations Handling Hazardous Substances Regulations 1982, 1983

HS(R) 17	Guide to the Classification and Labelling of Explosives Regulations 1983, 1983
HS(R) 18	Administrative guidance on the application of the European Community 'Low Voltage' Directive (73/23/EEC) to electrical equipment for use at work in the United Kingdom, 1984
HS(R) 19	Guide to the Asbestos (Licensing) Regulations 1983, 1984
HS(R) 21	Guide to the Control of Industrial Major Accident Hazards Regulations 1984, 1985
HS(R) 22	Guide to the Classification, Packaging and Labelling of Dangerous Substances Regulations 1984, 1985
HS(R) 23	Guide to the Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1985, 1986
HS(R) 24	Guide to the Road Transport (Carriage of Dangerous Substances in Packages, etc.) Regulations 1986, 1987
HS(R) 25	Memorandum of guidance on the Electricity at Work Regulations 1989, 1989
HS(R) 27	A Guide to Dangerous Substances in Harbour Regulations 1987, 1988
HS(R) 29	Notification and marking of sites. The Dangerous Substances (Notification and Marking of Sites) Regulations, 1990
HS(R) 30	A Guide to the Pressure Systems and Transportable Gas Containers Regulations 1989, 1990

Hazard Analysis Reports

HA 1	Canvey: A Second Report – A Summary of a Review of Potential Hazards from Operations in the Canvey Island/Thurrock Area Three Years after Publication of the Canvey Report, 1981
HA 2	Canvey: A Second Report – A Review of Potential Hazards from Operations in the Canvey Island/Thurrock Area Three Years after Publication of the Canvey Report, 1981
HA 3	Sizewell B: A Review by HM Nuclear Installations Inspectorate of the Preconstruction Safety Report, 1982
HA 4	PWR: A Report by the Health and Safety Executive to the Secretary of State for Energy on a Review of the Generic Safety Issues of Pressurised Water Reactors, 1979
HA 5	Nuclear Safety: Safety Assessment Principles for Nuclear Power Reactors, 1979

Health and Safety at Work Booklets (not in current list)

1	Lifting and Carrying
3	Safety Devices for Hand and Foot Operated Presses, 1971
4	Safety in the Use of Abrasive Wheels
6A	Safety in Construction Work: General Site Safety Practice
6B	Safety in Construction Work: Roofing
6C	Safety in Construction Work: Excavations
6D	Safety in Construction Work: Scaffolding
6E	Safety in Construction Work: Demolition
6F	Safety in Construction Work: System Building
10	Fire Fighting in Factories, 1970
13	Ionizing Radiations: Precautions for Industrial Users, 1970
14	Safety in the Use of Mechanical Power Presses
18	Industrial Dermatitis: Precautionary Measures
20	Drilling Machines: Guarding of Spindles and Attachments
22	Dust Explosions in Factories, 1970
24	Electrical Limit Switches and Their Applications, 1970
25	Noise and the Worker, 1971
27	Precautions in the Use of Nitrate Salt Baths, 1971
28	Plant and Machinery Maintenance, 1970
29	Carbon Monoxide Poisoning: Causes and Prevention
30	Storage of Liquefied Petroleum Gas at Factories, 1973
31	Safety in Electrical Testing
32	Repair of Drums and Small Tanks
33	Safety in the Use of Guillotines and Shears
34	Guide to the Use of Flame Arresters and Explosion Reliefs, 1965
35	Basic Rules for Safety and Health at Work, 1975
36	First Aid in Factories
37	Liquid Chlorine
38	Electric Arc Welding, 1970
40	Means of Escape in Case of Fire in Offices, Shops and Railway Premises
41	Safety in the Use of Woodworking Machines, 1970
42	Guarding of Cutters of Horizontal Milling Machines
44	Asbestos: Health Precautions in Industry, 1970
46	Evaporating and Other Ovens, rev., 1974
47	Safety in the Stacking of Materials, 1971

HSE Leaflets

HSE 1	After Flixborough?, 1976
HSE 2	Flixborough, the lessons to be learned, 1976
HSE 5	Introduction to the Employment Medical Advisory Service, 1985; rev., 1992
HSE 8	Fires and explosion due to the misuse of oxygen, 1984
HSE 9	Area office information services, 1986
HSE 11	Reporting of an injury or a dangerous occurrence, rev., 1986
HSE 16	Law on health and safety at work: essential facts for small business and the self-employed, 1986
HSE 17	Reporting a case of disease: a brief guide to the Reporting of Injuries, Diseases and Dangerous Occurrences Regulations 1985, 1986
HSE 21	Report that accident, 1988
HSE 22	The specialists, 1988; rev., 1992
HSEL 1	HSELINE: the new computerised source of health and safety at work references, 1983; rev., 1990

Industrial Advisory Committee Leaflets

IAC/L1 Guidance on the implementation of safety policies, 1982

IND(G) Leaflets

IND(G) 1 (L)	Obligations on importers of machinery, plant and substances in Great Britain, 1982
IND(G) 17 (L)	Asbestos and you, 1984

IND(G) 22 (L)	Danger! transport at work, 1985
IND(G) 30 (L)	Buried cables – beware!, 1985
IND(G) 35 (L)	Hot work on tanks and drums, 1985
IND(G) 39 (L)	Permits to work and you, 1986
IND(G) 64 (L)	Hazard and risk explained, 1989
IND(G) 65 (L)	Introducing COSHH, 1989
IND(G) 67 (L)	Introducing assessment, 1989 (The last three constitute the COSHH leaflet 'package')
IND(G) 78 (L)	Transport of LPG cylinders by road, 1990
IND(G) 96 (L)	Are you involved in the transport of dangerous substances by road?, 1990
IND(G) 98 (L)	Permit-to-work systems, 1992
IND(G) 115 (L)	New explosives controls, 1991
IND(G) 117 (L)	Policy statement on publication of reports of accidents, 1991
IND(G) 118 (L)	Policy statement on standards, 1991
IND(G) 119 (L)	Safer representatives and safety committees on offshore installations, 1991

L Series
See Table 3.5
This series is gradually superseding the HS(R) and COP series

Major Hazards	*Item*
Advisory Committee on Major Hazards. First Report, 1976	1
Assessment of the hazard from radio frequency ignition at the Shell and Esso sites at Braefoot Bay and Mossmorran, Fife, 1978	2
Report of the Steering Committee on radio ignition hazards at St Fergus, Scotland, 1979	3
Safety evaluation of the proposed St Fergus to Mossmorran natural gas liquids and St Fergus to Boddam gas pipelines, 1978	4
A reappraisal of the HSE safety evaluation of the proposed St Fergus to Mossmorran NGL pipeline, 1980	5
Advisory Committee on Major Hazards. Second Report, 1979	6
Advisory Committee on Major Hazards. Third Report, 1984	7
Names and addresses of sites sent to the Health and Safety Executive under Regulation 7 of the Control of Industrial Major Accident Hazards Regulations 1984 (CIMAH) or deemed to have been sent under Regulation 7(3) by means of a notification already made in accordance with Regulations 3(1) of the Notification of Installations Handling Hazardous Substances Regulations 1982 (NIHHS), 1986	8
Quantified risk assessment: its input to decision-making, 1989	9
Risk criteria for land use planning in the vicinity of major hazards, 1989	10

Medical Advice (not in current list)

MA 3	Control of lead at work: medical surveillance information and advice from the Health and Safety Executive's Medical Division
MA 4	Asbestos (Licensing) Regulations 1983: medical surveillance

Medical Series Leaflets (not in current list)

MS(A) 1	Lead and you, 1986
MS(A) 7	Cadmium and you, 1986
MS(A) 12	Hydrogen fluoride and you, 1990
MS(A) 13	Benzene and you, 1992
MS(A) 15	Silica dust and you, 1992
MS(A) 16	Chromium and you, 1991
MS(B) 1	Ulceration of the skin and inside the nose caused by chrome, 1974
MS(B) 5	Skin cancer caused by oil, 1983
MS(B) 6	Dermatitis and work (occupational dermatitis), 1983

Methods for the Determination of Hazardous Substances

MDHS 70	General methods for sampling airborne gases and vapours, 1990
MDHS 71	Analytical quality in workplace air monitoring, 1991
MDHS 72	Volatile organic compounds in air, 1992

Nuclear Installations	*Item*
Accident at Three Mile Island, 1979	1
Nuclear safety, 1979	2
PWR, 1979	3
Windscale. The management of safety, 1981	4
Emergency plans for civil nuclear installations, 1982	5
Work of HM Nuclear Installations Inspectorate, 1982	6
HM Nuclear Installations Inspectorate: a bibliography of published work 1962–1982, 1983	7
Safety assessment principles for nuclear chemical plant, 1983	8
Safety audit of BNFLs Sellafield, vols 1–2, 1986	9
Comments received on the tolerability of risk from nuclear power stations, 1988	10
The tolerability of risks from nuclear power stations, 1988 (not in current list)	11
An examination of the CEGB's R6 procedure for the assessment of the integrity of structures containing defects, 1989	12
ACSNI Study Group on Human Factors. First report on training and related matters, 1990	13
ACSNI Study Group on Human Factors. Second report: Human Reliability Assessment – a critical overview, 1991	14
A review of American nuclear emergency planning, 1991	15
Safety assessment principles for nuclear plants, 1992	16
The tolerability of risks from nuclear power stations, 1992	17
ACSNI Study Group on Human Factors. Third report: Organizing for safety, 1993	18

Sizewell B	*Item*
Sizewell B, 1982	19
Appraisal of the current situation on large LOCA calculations in the context of Sizewell B, 1984	20

Sizewell B public inquiry

NII/P/1	Sizewell B public inquiry: proof of evidence on the work and responsibilities of HM Nuclear Installations Inspectorate, 1983 (plus additional material denoted ADD1, ADD2, etc.)

NII/P/2	Sizewell B public inquiry: proof of evidence on HM Nuclear Installations Inspectorate's view of the Central Electricity Generating Board's safety case, 1983 (plus additional material denoted ADD1, ADD2, etc.)
NII/S/2	Sizewell B inquiry: the Inspectorate's approach to the assessment of code validation submissions, 1983
NII/S/4	Sizewell B inquiry: schedule of NII reservations and issues all of which require to be resolved to the Inspectorate's satisfaction prior to licensing, 1983
NII/S/5	Sizewell B power station public inquiry: safety case computer codes – categorisation and validation assessment, 1983
NII/S/83	Sizewell B power station inquiry: relationship between the NII's assessment principles and levels of risk, 1984
NII 01	Sizewell B: a review by HM Nuclear Installation Inspectorate SUPP 1 Degraded core analysis, 1982 SUPP 2 Safety analysis, 1982 SUPP 3 External hazards – aircraft crash, 1983 SUPP 6 Reactor protection system, 1983 SUPP 7 External hazards – earthquake, 1983 SUPP 8 External hazards – fire, 1983 SUPP 9 Code validation for LOCA, 1983 SUPP 10 Reactor pressure vessel, 1983 SUPP 11 Pressure circuit components, 1983 SUPP 12 ALARP strategy for dose reduction, 1983 SUPP 13 Human factors, 1983 SUPP 14 Quality assurance, 1983
HA 3	Sizewell B: a review by HM Nuclear Installations Inspectorate of the preconstruction safety report, 1982

Occasional Papers

OP 1	Problem drinker at work, 1981
OP 2	Microprocessors in industry: safety implications of the use of programmable electronic systems in factories, 1981
OP 3	Managing safety, 1981
OP 5	Electrostatic ignition: hazards of insulating materials, 1982
OP 9	Monitoring safety
OP 10	Safety of electrical distribution systems in factories, 1985
OP 11	Measuring the effectiveness of HSE's field activities, 1985

Offshore Technology Reports

OTH 91 337	Pipeline and riser loss of containment study, 1990 (PARLOC 90)
OTH 92 389	Human factors, shift work and alertness in the offshore industry, 1993
OTI 92 585	Generic foundation data to be used in the assessment of blast and fire scenarios and typical structural details for primary, secondary and supporting structures and components, 1992
OTI 92 586	Representative range of blast and fire scenarios, 1992
OTI 92 587	The prediction of single and two-phase release rates, 1992
OTI 92 588	Legislation, codes of practice and certification requirements, 1992
OTI 92 589	Experimental facilities suitable for use in studies of fire and explosion hazards in offshore structures, 1992
OTI 92 590	The use of alternative materials in the design and construction of blast and fire resistant structures, 1992
OTI 92 591	Gas/vapour build up on offshore structures, 1992
OTI 92 592	Confined vented explosions, 1992
OTI 92 593	Explosions in highly congested volumes, 1992
OTI 92 594	The prediction of the pressure loading on structures resulting from an explosion, 1992
OTI 92 595	Possible ways of mitigating explosions on offshore structures, 1992
OTI 92 596	Oil and gas fires: characteristics and impact, 1992
OTI 92 597	Behaviour of oil and gas fires in the presence of confinement and obstacles, 1992
OTI 92 598	Current fire research: experimental, theoretical and productive modelling resources, 1993
OTI 92 599	The effects of simplifications of the explosion pressure – time history, 1988
OTI 92 601	Computerised analysis tools for assessing the response of structures subjected to blast loading, 1992
OTI 92 602	The effects of high strain rate on material properties, 1992
OTI 92 603	Analysis of projectiles, 1992
OTI 92 604	Experimental data relating to the performance of steel components at elevated temperatures, 1992
OTI 92 605	Methodologies and available tools for the design/analysis of steel components at elevated temperatures, 1992
OTI 92 606	Passive fire protection: performance requirements and test methods, 1992
OTI 92 607	Availability and properties of passive and active fire protection systems, 1992
OTI 92 608	Existing fire design criteria for secondary, support and system steelwork, 1992
OTI 92 610	Thermal response of vessels and pipework exposed to fire, 1992

Oil Industry	*Item*
A guide to the principles and operation of permit-to-work procedures as applied to the petroleum industry, 1986	1

Guidelines for occupational health services in the oil industry, 1987	2
Guidance on health and safety monitoring in the petroleum industry, 1992	3
Guidance on multiskilling in the petroleum industry, 1992	4
Guidance on permit-to-work systems in the petroleum industry, 1991	5
Offshore installations guidance notes: consolidated edition, 4th ed., 1990–	6

Promotional Leaflets

PML 6	New regulations on packaging and labels for dangerous substances: Classification, Packaging and Labelling of Dangerous Substances Regulations 1984, 1985
PML 7	Deadly maintenance: a study of fatal accidents at work, 1985
PML 10	Monitoring safety, 1986

Research Papers

RP 1	Examination of entrained air-flow rate data for large-scale water spray installations by J. McQuaid, 1978
RP 7	Decay of spherical detonations and shocks by H. Phillips, 1980
RP 8	Dispersion of heavier-than-air gases in the atmosphere: review of research, and progress report on HSE activities by J. McQuaid, 1978
RP 11	Comparative risks of electricity production systems: a critical survey of the literature by A.V. Cohen and D.K. Pritchard, 1980
RP 18	Reproducibility of asbestos counts by T.L. Ogden, 1982
RP 24	Dispersion of heavier-than-air gases in the atmosphere: a review of the organization and management of the HSE field trials 1982/84 by D.G. Wilde, 1984
RP 32	First aid retention of knowledge survey by M.C. Cullen, 1992

Research Reviews	*Item*
Shift work and health by J.M. Harrington, 1978	1
Manual handing and lifting by J.D.G. Troup and F.C. Edwards, 1985	2
Alternatives to asbestos products: a review, 1986	3

Safety Health and Welfare Leaflets

SHW 29	Phenol poisoning (cautionary notice), 1984
SHW 367	Dermatitis (cautionary notice), 1975
SHW 385	Cyanide poisoning (cautionary notice), 1983
SHW 395	Gassing and chemical burns (cautionarynotice), 1984
SHW 397	Effects of mineral oil on the skin (cautionary notice), 1982
SHW 830	Dust explosions in factories, 1975
SHW 849	Nitrate salt baths (cautionary notice), 1975
SHW 932	Dangers from carbon monoxide (cautionary notice), 1981
SHW 2125	Danger and explosion in oil storage tanks fitted with immersed heaters (cautionary notice), 1981

Sector Guidance

See Asbestos, Dangerous Substances, Major Hazards, Nuclear Installations, Oil Industry

Specialist Inspectors Reports

SIR 5	Avoiding water hammer in steam systems by S. Mortimer and D.C. Edwards, 1988
SIR 8	The National Exposure Data Base – a computer record system for occupational hygiene data by P.L. Beaumont, D.K. Burns and T.E. Taylor
SIR 9	The fire and explosion hazards of hydraulic accumulators by D.B. Pratt
SIR 16	Low volume, high velocity extraction systems by B. Fletcher
SIR 19	Fire and explosion hazards associated with the storage and handling of hydrogen peroxide by R. Merrifield
SIR 21	Assessment of the toxicity of major hazard substances by R.M. Turner and S. Fairhurst

Technical Data Notes (not in current list)

1	Dust control – the low volume, high velocity system, 2nd rev., 1976
2/73	Threshold limit values for 1975, 1976
3	Occupational cancer of the renal tract, rev., 1973
4	Stibine – health and safety precautions, 1976
5	Antimony – health and safety precautions, 1975
6	Arsine – health and safety precautions, 1975
7	Phosphine – health and safety precautions, 1975
8	Chromium – health and safety precautions, 1973
9	Arsenic – health and safety precautions
10	Aniline – health and safety precautions
11	Cadmium – health and safety precautions, rev., 1975
12	Notes for the guidance of designers on the reduction of machinery noise, 1975
13	Standards for asbestos dust concentration for use with Asbestos Regulations 1969, rev., 1974
14	Health – dust in industry
15	Methyl bromide – health and safety precautions
16	Prevention of industrial lead poisoning
17	Trichloroethylene, rev., 1973
18	The safe cleaning repair and demolition of large tanks for storing flammable liquids, rev., 1975
19	Ventilation of buildings: fresh air requirements, rev., 1975
20	Anthrax
21	Mercury, rev., 1975
24	Asbestos Regulations 1969: respiratory protective equipment, 2nd rev., 1975
25	Safe operation of automatically controlled steam and hot water boilers, 1975
26	Erection and dismantling of tower cranes, 1973
27	Access to tower cranes, 1974
29	Fire risk in the storage and industrial use of cellular plastics, rev., 1975

32 Guarding of portable pipe threading machines
33 Power press mechanisms: overrun and fall-back devices
35 Control of asbestos dust, 1975
36 Safety in the use of cartridge operated fixing tools
38 Tripping device for radial and heavy vertical drilling machines
40 Standards for chromic acid concentration in air for use with the chromium plating regulations
41 Isocyanates – toxic hazard and precautions, 1975
42 Probable asbestos dust concentration at construction processes
43 Technical level training: code of practice for reducing the exposure of employed persons to noise, 1976
44 Road transport in factories, 1973
45 Industrial use of flammable gas detectors, 1973
46 Safety at quick opening and other doors of autoclaves, 1974
47 Entry into confined spaces: hazards and precautions, 1975
48 Permissible opening in fixed guards
53/1 Zinc embrittlement of austenitic stainless steel, 1976
53/2 Nitrate stress corrosion of mild steel, 1976
53/3 Creep of metals at elevated temperatures, 1977

Technical Information Leaflets

Engineering and metallurgy
EM 2 Metallurgical examination of broken and defective equipment, 1980
EM 3 Mechanical testing facilities at Sheffield, 1980
EM 4 Fracture mechanics of low and medium-strength steel, 1980
EM 5 Fatigue crack initiation and propagation in steels, 1980
EM 7 Design considerations for mechanical components, 1980

Environmental contaminants
EC 3 Catalytic gas sensing elements: their use in gas monitoring, 1980
EC 4 Diffusive sampler for organic gases and vapours in air, 1980

Frictional ignition
FI 2 Frictional sparking risk with light metals and their alloys, 1980

General
G 1 Health and Safety Laboratories – an introduction, 1980

Hazard analysis
HA 1 Safety aspects of industrial maintenance, 1982

Machine safety
MS 1 Measurement of the dynamic performance of machines and their safety systems, 1980

Respiratory apparatus
RA 1 Filter self-rescuers, 1979

Also series on Electrical hazards, Explosions, Protective equipment, Special instruments and techniques

Technical Papers
TP 1 Examination of entrained air flow rate data for large scale water spray installations by J. McQuaid, 1978 (also referenced as RP 1)
TP 7 Decay of spherical detonations and shocks by H. Phillips, 1980 (also referenced as RP 7)

Toxicity Reviews

TR 1	Styrene, 1981
TR 2	Formaldehyde, 1981
TR 3	Carbon disulphide, 1981
TR 4	Benzene, 1982
TR 20	Toluene, 1989
TR 26	Xylenes, 1992
TR 30	Phosphorous compounds, 1994

Toxicology of Substances in Relation to Major Hazards

		Item
1989	Acrylonitrile by R.M. Turner and S. Fairhurst	1
1990	Ammonia by M.P. Payne, J. Delic and R.M. Turner	2
1990	Chlorine by R.M. Turner and S. Fairhurst	3
1990	Hydrogen Fluoride by R.M. Turner and S. Fairhurst	4
1990	Hydrogen Sulphide by R.M. Turner and S. Fairhurst	5
1992	Sulphuric Acid Mist by R.M. Turner and S. Fairhurst	6
1993	Hydrogen Fluoride, rev., by M. Meldrum	7

Translations
including documents on Seveso, German Risk Study (Risikostudie) and German Order on Hazardous Substances (Störfallverordnung)

Highway Accident Reports

HAR-71-06	Liquid Oxygen Tank Truck Explosion Followed by Fires in Brooklyn, New York, May 30, 1970
HAR-71-07	Accidental Mixing of Incompatible Chemicals, Followed by Multiple Fatalities, During a Bulk Delivery, Berwick, Maine, April 2, 1971
HAR-72-03	Truck–Automobile Collision Involving Spilled Methyl Bromide on US 90 near Gretna, Florida, August 8, 1971
HAR-72-05	Automobile–Truck Collision Followed by Fire and Explosion of Dynamite Cargo on US Highway 78, near Waco, Georgia, June 4, 1971
HAR-73-03	Propane Tractor Semitrailer Overturn and Fire, US Route 501, Lynchburg, Virginia,March 9, 1972
HAR-73-04	Multiple Vehicle Collision, Followed by Propylene Cargo Tank Explosion, New Jersey Turnpike, Exit 8, September 21, 1972
HAR-76-04	Surtigas SA, Tank-Semitrailer Overturn, Explosion and Fire, near Eagle Pass, Texas, April 29, 1975
HAR-76-07	Union Oil Company of California, Tank Truck and Full Trailer Overturn and Fire, Seattle, Washington, December 4, 1975
HAR-77-01	Transport Company of Texas, Tractor Semitrailer (Tank) Collision with Bridge Column and Sudden Dispersal of Anhydrous Ammonia Cargo, Houston, Texas, May 11,1976
HAR-78-04	Usher Transport Inc., Tractor–Cargo–Tank–Semi-Trailer Overturn and Fire, Beattyville, Kentucky, September 24, 1977
HAR-80-05	Multiple Vehicle Collision and Fire, US Route 101, Los Angeles, California, March 3,1980
HAR-83-01	Multiple Vehicle Collisions and Fire,Caldecott Tunnel, Oakland, California, April 7, 1982

Marine Accident Reports

MAR-74-01	Tank Barge IOS-3301, Port Jefferson, New York, January 10, 1972
MAR-75-03	Tank Barge *Ocean 89*, Fire and Explosions, Carteret, New Jersey, October 25, 1972
MAR-75-05	Tankship *Texaco North Dakota*, Pumproom Explosion, Gulf of Mexico, October 3, 1973
MAR-78-01	US Tankship SS *Marine Floridan* Collision with Benjamin Harrison Memorial Bridge, Hopewell, Virginia, February 24, 1977
MAR-78-02	Tank Barge B-924 Fire and Explosion with Loss of Life at Greenville, Mississippi, November 13, 1975
MAR-78-06	Liberian Tankship SS *Sansinena* Explosion and Fire, Union Oil Terminal Berth 46, Los Angeles, California, December 17, 1976
MAR-78-09	Collision of Liberian Tankship M/V *Stolt Viking* and US Crewboat *Candy Bar* in Gulf of Mexico, January 7, 1978
MAR-78-10	French Tankship SS *Sitala* Collision with Moored Vessels, New Orleans, Louisiana, July 28, 1977
MAR-79-04	Luling Destrehan Ferry M/V *George Prince* Collision with the Tanker SS Frosta on the Mississippi River, October 20, 1976
MAR-79-05	Capsizing and Sinking of the Self-Elevating Mobile Offshore Drilling Unit *Ocean Express* near Port O'Conner, Texas, April 15, 1976
MAR-79-06	USS *LY. Spear* (AS-36) Collision with Liberian Motor Tankship *Zephyros*, Lower Mississippi River, February 22, 1978
MAR-79-13	US Motor Tankship *Sealift China Sea* Ramming of the Italian Motor Cargo Vessel *Lorenzo D'Amico*, Los Angeles, California, January 15, 1978
MAR-79-15	Spanish Motor Tankship *Ribaforada* Ramming of Barge MB-5, Three Wharves and Cargo Ship M/V *Tiaret*, New Orleans, Louisiana, December 4, 1977
MAR-79-16	Collision of American Containership SS *SeaLand Venture* and Danish Tanker M/T *Netty Maersk*, Inner Bar Channel, Galveston, Texas, August 27, 1978
MAR-80-07	Collision of Peruvian Freighter M/V *Inca Tupac Yupanqui* and US Butane Barge *Panama City*, Good Hope, Louisiana, August 30, 1979
MAR-80-11	Collision of US Tankship SS *Exxon Chester* and Liberian Freighter M/V *Regal Sword* in the Atlantic Ocean near Cape Cod, Massachusetts, June 18, 1979
MAR-80-12	Liberian Tank Vessel M/V *Seatiger* Explosion and Fire, Sun Oil Terminal, Nederland, Texas, April 19, 1979
MAR-80-14	Collision of US Coast Guard Cutter*Blackhorn* and US Tankship *Capricorn*, Tampa Bay, Florida, January 28, 1980
MAR-80-17	Collision of Liberian Tankship M/V *Pina* and the Towboat *Mr Pete* and its Tow, Mile 99.3 Lower Mississippi River, December 19, 1979
MAR-80-18	Explosion and Fire on board the SS *Chevron Hawaii* with Damages to Barges and Deer Park Shell Oil Company Terminal Houston Ship Channel, September 1, 1979
MAR-81-04	Tankship SS *Texaco North Dakota* and Artificial Island EI-361-A, Collision and Fire, Gulf of Mexico, August 21, 1980

MAR-81-05	Collision of US Mississippi River Steamer *Natchez* and US Tankship SS *Exxon Baltimore*, New Orleans, Louisiana, March 29, 1980
MAR-81-11	Grounding of US Tankship SS *Concha Constable Hook*, Reach of Kill Van Kull,Upper New York Harbor, January 19, 1981
MAR-81-12	Liberian Chemical Tankship M/V *Coastal Transport* Collision with US Offshore Supply Vessel M/V *Sallee* P, Lower Mississippi River, near Venice, Louisiana, November 24, 1980
MAR-81-14	Explosion and Fire on board the US *Tankship Monticello Victory*, Port Arthur, Texas, May 31, 1981
MAR-82-02	Collision of the US Tankship *Pisces* with the Greek Bulk Carrier *Trade Master*, Mile 124,Lower Mississippi River, December 27, 1980
MAR-83-02	Capsizing and Sinking of the US Mobile Offshore Drilling Unit *Ocean Ranger* off the East Coast of Canada, 166 N Miles E of St John's, Newfoundland, February 15, 1983
MAR-83-03	Explosion and Fire on board US Coastal Tankship *Poling Bros* No.9 East River, New York Harbor, February 26, 1982
MAR-83-04	Collision of US Towboat *Creole Genii* and Liberian Tank Vessel Arkas near Mile 130,Mississippi River, March 31, 1982
MAR-83-06	Engine Room Flooding and Near Foundering of US Tankship *Ogden Williamette*, Caribbean Sea, June 16, 1982
MAR-83-07	Explosions and Fire on board the US Tankship SS *Golden Dolphin* in the Atlantic Ocean, March 6, 1982
MAR-84-08	See MAR-87-02
MAR-84-09	Grounding of the US Tankship SS *Mobil Oil* in the Columbia River, near Saint Helens,Oregon, March 19, 1984
MAR-85-04	Collision of the US Towboat *Ann Brent* and Tow with the Greel Tankship *Maninia*, Mile 150, Lower Mississippi River, June 11, 1984
MAR-85-06	Explosion and Sinking of the United States Tankship SS *American Eagle*, Gulf of Mexico,February 26 and 27, 1984
MAR-85-11	Explosion and Fire aboard the US Mobile Offshore Drilling Unit *Zapata Lexington*, Gulf of Mexico, September 14, 1984
MAR-86-03	Explosion and Fire on board the US Mobile Offshore Drilling Unit *Glomar Arctic II* in the North Sea, 130 Nautical Miles E-SE Aberdeen, Scotland, January 15, 1985
MAR-86-05	Explosion and Fire on board US Chemical Tankship *Puerto Rican* in the Pacific Ocean near San Francisco, California, October 31, 1984
MAR-86-10	Collapse of the US Mobile Offshore Drilling Unit *Penrod 61* in the Gulf of Mexico, October 27, 1985
MAR-87-02	Capsizing and Sinking of the US Drillship *Glomar Java Sea* in the South China Sea 65 Nautical Miles South-Southwest of Hainan Island, People's Republic of China, October 25, 1983 (supersedes MAR-84-08)
MAR-87-05	Explosion aboard the US Tank Barge TTT 103, Pascagoula, Mississippi, July 31, 1986
MAR-87-06	Explosions and Fire aboard the US Tankship *Omi Yukon* in the Pacific Ocean about 1000 Miles West of Honolulu, Hawaii, October 28, 1986
MAR-87-07	Engineroom Flooding of the US Tankship *Prince William Sound*, near Puerto Vallarta, Mexico, May 9, 1986
MAR-87-08	Fires on board the Panamanian Tankship *Shoun Vanguard* and the US Tank Barge *Hollywood* 3013, Deer Park, Texas, October 7, 1986
MAR-87-09	Explosion and Fire aboard the US Tank Barge STC 410 at the Steuart Petroleum Company Facility, Piney Point, Maryland, December 20, 1986
MAR-87-10	Grounding of the Panamanian Tankship *Grand Eagle* in the Delaware River, near Marcus Hook, Pennsylvania, September 28, 1985
MAR-88-09	Ramming of the Maltese Bulk Carrier *Mont Fort* by the British Tankship *Maersk Neptune* in Upper New York Bay, February 15, 1988
MAR-89-02	Striking of a Submerged Object by Bahamian Tankship *Esso Puerto Rico*, Mississippi River, Kenner, Louisiana, September 3, 1988
MAR-89-03	Explosion aboard the Maltese Tank Vessel *Fiona* in the Long Island Sound near Northport, New York, August 31, 1988
MAR-89-06	Capsizing and Sinking of the Mobile Offshore Drilling Unit *Rowan Gorilla I* in the North Atlantic Ocean, December 15, 1988
MAR-89-07	Collision between the Swedish Auto Carrier *Figaro* and the French Tankship *Camarque*, Galveston Bay Entrance, November 10, 1988
MAR-90-04	Grounding of the US Tankship *Exxon Valdez* on Bligh Reef, Prince William Sound near Valdez, Alaska, March 24, 1989
MAR-90-06	Engineroom Fire aboard the US Tankship *Charleston* in the Atlantic Ocean about 35 miles off the South Coast, March 7, 1989
MAR-91-01	Grounding of the Greek Tankship *World Prodigy* off the Coast of Rhode Island, June 23, 1989
MAR-91-03	Collision between the Greek Tankship *Shinoussa* and the US Towboat *Chandy N* and Tow near Red Fish Island, Galveston Bay, Texas
MAR-91-04	Explosion and Fire aboard the US Tankship *Jupiter*, Bay City, Michigan, September 16, 1990
MAR-92-01	Grounding of the US Tankship *Star Connecticut*, Pacific Ocean, near Barbers Point, Hawaii, November 6, 1990
MAR-92-02	Explosion and Fire on the US Tankship *Surf City*, Persian Gulf, February 22, 1990
MAR-92-04	Collision of the Hong Kong-Registered Motor Tankship *Mandan* with the US Army Corps of Engineers Barge Flotilla at Mile 10.5 above Head of Passes in the Lower Mississippi River near Venice, Louisiana, August 15, 1990

Pipeline Accident Reports

PAR-71-01	Mobil Oil Corporation High-Pressure Natural Gas Pipeline, near Houston, Texas, September 9, 1969
PAR-71-02	Colonial Pipeline Co., Petroleum Products Pipeline, Jacksonville, Maryland, September 3, 1970
PAR-72-01	Phillips Pipeline Company, Propane Gas Explosion, Franklin County, Missouri, December 9, 1970
PAR-73-02	Exxon Pipeline Company, Crude Oil Explosion at Hearne, Texas, May 14, 1972
PAR-73-04	Phillips Pipeline Company, Natural Gas Liquids Fire, Austin, Texas, February 22, 1973
PAR-74-06	Mid-America Pipeline System, Anhydrous Ammonia Leak, Conway, Kansas, December 6, 1973
PAR-75-01	Michigan-Wisconsin Pipeline Company, Natural Gas Transmission Line Failure, Monroe, Louisiana, March 2, 1974
PAR-75-02	Transcontinental Gas Pipeline Corporation, 30 inch Transmission line Failure, near Bealeton, Virginia, June 9, 1974
PAR-76-01	Mid Valley Pipeline Company, Crude Oil Terminal Fire, near Lima, Ohio, January 17, 1975
PAR-76-05	Dow Chemical Company USA, Natural Gas Liquids Explosion and Fire, near Devers, Texas, May 12, 1975
PAR-76-07	Sun Pipeline Company, Rupture of 8 inch Pipeline, Romulus, Michigan, August 2, 1975
PAR-77-03	Exxon Gas System Inc., Natural Gas Explosion and Fire, Robstown, Texas, December 7, 1976
PAR-78-01	Consolidated Gas Supply Corporation, Propane Pipeline Rupture and Fire, Ruff Creek, Pennsylvania, July 20, 1977
PAR-78-02	Alyeska Pipeline Service Company, Explosion and Fire, Pump Station 8, near Fairbanks, Alaska, July 8, 1977
PAR-79-01	Mid-America Pipeline System, Liquefied Petroleum Gas Pipeline Rupture and Fire, Donnellson, Iowa, August 4, 1978
PAR-80-01	Southern Natural Gas Company, Rupture and Fire of a 14 inch Gas Transmission Pipeline South-East of New Orleans, Louisiana, July 15, 1980
PAR-80-02	Columbia liquefied Natural Gas Corporation, Explosion and Fire, Cove Point, Maryland,October 6, 1979
PAR-80-06	The Pipelines of Puerto Rico Inc., Petroleum Products Pipeline Rupture and Fire, Bayamon, Puerto Rico, January 30, 1980
PAR-83-01	The Gas Company of New Mexico, Natural Gas Explosion and Fire, Portales, New Mexico, June 28, 1982
PAR-83-02	Northern
PAR-83-02	Northern Natural Gas Company, Pipeline Puncture, Explosion and Fire, Hudson, Iowa, November 4, 1982
PAR-83-03	Mississippi River Transmission Corporation, Natural Gas Flash Fire, Pine Bluff, Arkansas, October 1, 1982
PAR-83-04	El Paso Natural Gas Company, Compressor Station Explosion and Fire, Bloomfield, New Mexico, May 26, 1983
PAR-84-01	Mid-America Pipeline System, liquefied Petroleum Gas Pipeline Rupture, West Odessa, Texas, March 15, 1983
PAR-85-01	Arizona Public Service Company, Natural Gas Explosion and Fire, Phoenix, Arizona, September 25, 1984
PAR-85-02	National Fuel Gas Company, Natural Gas Explosion and Fire, Sharpsville, Pennsylvania, February 23, 1985
PAR-86-01	Continental Pipe line Company, Pipeline Rupture and Fire, Kaycee, Wyoming, July 23, 1985
PAR-87-01	Texas Eastern Gas Pipeline Company Ruptures and Fires at Beaumont, Kentucky, on April 27, 1985, and Lancaster, Kentucky, on February 21, 1986
PAR-90-02	Fire on Board the F/V *Northumberland* and Rupture of a Natural Gas Transmission Pipeline in the Gulf of Mexico near Sabine Pass, Texas, October 3, 1989
PAR-91-01	Liquid Propane Pipeline Rupture and Fire, Texas Eastern Products Pipeline Company, North Blenheim, New York, March 3, 1990

Railroad Accident Reports

RAR	Southern Railway Company, Train 154, Derailment with Fire and Explosion, Laurel, Mississippi, January 25, 1969
RAR-70-02	Illinois Central Railroad Company, Derailment at Glendora, Mississippi, September 11, 1969
RAR-71-02	Chicago, Burlington and Quincy RR Company, Train 64 and Train 824, Derailment and Collision with Tank Car Explosion, Crete, Nebraska, February 18, 1969
RAR-72-02	Derailment of Toledo, Peoria and Western Railroad Company's Train No. 20 with Resultant Fire and Tank Car Ruptures, Crescent City, Illinois, June 21, 1970
RAR-72-06	Derailment of Missouri Pacific Railroad Company's Train 94 at Houston, Texas, October 19, 1971
RAR-73-01	Hazardous Materials Railroad Accident in the Alton and Southern Gateway Yard in East St Louis, Illinois, January 22, 1972
RAR-74-04	Derailment and Subsequent Burning of Delaware and Hudson Railway Freight Train at Oneonta, New York, February 12, 1974
RAR-75-02	Southern Pacific Transportation Company, Freight Train 2nd BSM 22 Munitions Explosion, Benson, Arizona, May 24, 1973
RAR-75-04	Hazardous Materials Accident in the Railroad Yard of the Norfolk and Western Railway at Decatur, Illinois, July 19, 1974

RAR-75-07	Hazardous Materials Accident at the Southern Pacific Transportation Company's Englewood Yard in Houston, Texas, September 21, 1974
RAR-76-01	Burlington Northern Inc., Monomethylamine Nitrite Explosion, Wenatchee, Washington, August 6, 1974
RAR-76-08	Derailment of Tank Cars with Subsequent Fire and Explosion on Chicago, Rock Island and Pacific Rail Company, near Des Moines, Iowa, September 1, 1975
RAR-77-07	Derailment of a Burlington Northern Freight Train at Belt, Montana, November 26, 1976
RAR-78-04	Louisville and Nashville Railroad Company, Freight Train Derailment and Puncture of Anhydrous Ammonia Tank Cars at Pensacola, Florida, November 9, 1977
RAR-78-07	Derailment of Atlanta and St Andrews Bay Railroad Company Freight Train, Youngstown, Florida, February 26, 1978
RAR-78-08	St Louis Southwestern Railway Company Freight Train Derailment and Rupture of Vinyl Chloride Tank Car, Lewisville, Arkansas, March 29, 1978
RAR-79-01	Derailment of L&N Railroad Company's Train No. 584 and Subsequent Rupture of Tank Car Containing Liquefied Petroleum Gas, Waverly, Tennessee, February 22, 1978
RAR-79-11	Louisville and Nashville Railroad Company, Freight Train Derailment and Puncture of Hazardous Materials Tank Cars, Crestview, Florida, April 8, 1979
RAR-81-01	Illinois Central Gulf Railroad Company Freight Train Derailment, Hazardous Material Release and Evacuation, Muldraugh, Kentucky, July 26, 1980
RAR-83-05	Derailment of Illinois Central Gulf Railroad Freight Train Extra 9629 East (GS-2-28) and Release of Hazardous Materials at Livingston, Louisiana, September 28, 1982
RAR-85-08	Vinyl Chloride Monomer Release from a Railroad Tank Car and Fire, Formosa Plastics Corporation Plant, Baton Rouge, Louisiana, July 30, 1983
RAR-85-10	Denver and Rio Grande Western Railroad Company Train Yard Accident Involving Punctured Tank Car, Nitric Acid and Vapor Cloud, Denver, Colorado, April 3, 1983
RAR-85-12	Derailment of Seaboard System Railroad Train No. F-690 with Hazardous Material Release, Jackson, South Carolina, February 23, 1985
RAR-86-04	Derailment of St Louis Southwestern Railway Company (Cotton Belt) Freight Train Extra 4835 North and Release of Hazardous Materials near Pine Bluff, Arkansas, June 9, 1985
RAR-89-04	Head-On Collision between Iowa Interstate Railroad Extra 406 East with Release of Hazardous Materials near Altoona, Iowa, July 30, 1988
RAR-89-05	Collision and Derailment of Montana Rail link Freight Train with Locomotive Units and Hazardous Materials Release, Helena, Montana, February 2, 1989
RAR-90-02	Derailment of Southern Pacific Transportation Company Freight Train on May 12, 1989, and Subsequent Rupture of Calney Petroleum Pipeline on May 25, San Bernadino, California
RAR-91-04	Derailment of CSX Transportation Inc. Freight Train and Hazardous Materials Release near Freeland, Michigan, July 22, 1989

Papers

9	The lag on ignition of firedamp by Naylor and Wheeler, 1925
36	The ignition of gases by hot wires by W.C.F. Shepherd and R.V. Wheeler, 1927
46	The ignition of firedamp by the heat impact of rocks by M.M.J. Burgess and R.V. Wheeler, 1928
54	The ignition of firedamp by the heat impact of metal against rock by M.M.J. Burgess and R.V. Wheeler, 1929
62	The ignition of firedamp by the heat impact of hand picks against rocks by M.M.J. Burgess and R.V. Wheeler, 1930
70	The ignition of firedamp by the heat of coal cutter picks against rocks by M.M.J. Burgess and R.V. Wheeler, 1931
74	International Conf. on Safety in Mines at Buxton
93	The ignition of firedamp by compression by Dixon and Harwood, 1935

Safety in Mines Research Establishment

(Sheffield)

Electrical hazards

1	Testing of intrinsically safe electrical equipment
2	Research on flameproof enclosures for electrical equipment
3	On-load testing of flameproof electrical equipment
4	Arc physics
5	Ignition of flammable gases by arc discharges

6 High-voltage equipment for use in flammable atmospheres
7 Testing of types e and N electrical equipment and testing of flameproof electrical equipment

Engineering and metallurgy
2 Strength and energy absorption of wire ropes under impulsive loading
3 Deterioration of wire ropes
4 Metallurgical examination of faulty equipment
5 Fatigue properties of chains
6 Mechanical test facilities

Explosion
Prevention of explosions in pulverised fuel systems
1 Fires in rigid polyurethane foam
3 Small-scale flammability tests
6 Behaviour of high-expansion foam in storage tanks

Frictional ignition
2 Frictional ignition tests with boot studs
3 Firedamp ignition hazards from light alloys
4 Firedamp ignition by hot surfaces produced by impact and friction
5 The ignition hazard from glass

Gas detection
1 Use of a metallized membrane electrode in the monitoring of oxygen, carbon monoxide and other gases
2 Catalytic oxygen-deficiency detector
3 Infra-red hydrocarbon detector
4 Fluorescence-quenching oxygen monitor
5 A non-ambiguous catalytic detector for methane
6 Gas detection with semiconductor metal oxides
7 Circuitry techniques in a catalytic carbon-monoxide detector
8 Circuitry techniques in a flashing methane alarm
9 Circuitry techniques in a combustible-gas alarm
10 The oxygen-deficiency hazard and its detection
11 Gas detection with catalytic elements

Incident investigation
1 Use of small-scale models in the investigation of mine explosions

Research Reports
17 Ignition hazards associated with the use of a buffing machine underground by H. Robinson, P.B. Smith and H.L. Williams, 1951
42 The ignition of firedamp by friction by A.H.A. Wynn, 1952
59 Sparks from aluminium paint: the firedamp ignition hazard by C.S.W. Grice, 1952
75 The ignition hazard from sparks of magnesium-base alloys by S.N.A Margerson *et al,* 1953
90 The ignition hazard from sparks from cast alloys of magnesium and aluminium by H. Titman, 1954
95 The ignition of explosive gas mixtures by friction by H. Titman and A.H.A. Wynn, 1954
129 The ignition of explosive gas mixtures by small combustible particles. Pt 1, Ignition by particles of pyrophor bar by D. Rae, 1956
177 The ignition of gas by the impact of light alloys on oxide-coated surfaces by D. Rae, 1959
190 The ignition of methane-air by the glancing impact of metals on smears of light alloys formed on rusty surfaces by D. Rae, 1960
192 Incendive frictional sparking from alloys containing aluminium by D. Rae and B.J. Nield, 1960
223 The role of quartz in the ignition of methane by friction of rocks by D. Rae, 1964
224 The size and temperature of a hot square in a cold plane surface necessary for the ignition of methane by D. Rae, B. Singh and R. Danson, 1964
229 The ignition of gas by the impact of brass against magnesium anodes and other parts of a ship's tank by D. Rae, 1965
231 Ignition of firedamp by means other than electricity and explosives by H.F. Coward and H.T. Ramsay, 1965
236 The importance of rates of working and wear processes on the ignition of methane by friction by D. Rae, 1966
240 Ignition of methane by electrical discharges by D.W. Widginton, 1966
256 Some aspects of the design of intrinsically safe circuits by D.W. Widginton, 1968

Reports in AHSB, AHSB(RP) and SRS/GR series are prefaced in text by UKAEA, other series are not

AHSB(RP)

AHSB(RP) R42	1964	Methods of estimation of the dispersion of windborne material and data to assist in their application by P.M. Brynt

AHSB series

AHSB(S) R64	1963	An assessment of environmental hazards from fission product releases by J.R. Beattie
AHSB(S) R91	1965	Reliability considerations for automatic protective systems by A.E. Green and A.J. Bourne
AHSB(S) R99	1965	Reliability assessment of protective systems for nuclear installations by AR. Eames
AHSB(S) R110	1966	A criterion for the reliability assessment of protective systems by A.J. Bourne
AHSB(S) R113	1966	Assessment of sensing channels for high integrity protective systems by A.E. Green
AHSB(S) R117	1966	Safety assessment with reference to automatic protective systems for nuclear reactors, Pts 1-3, by A.E. Green and AJ. Bourne
AHSB(S) R119	1966	The use of detailed fault analysis in evaluating fail-safe equipment by A.R. Eames
AHSB(S) R122	1967	The response times of protective systems for nuclear and chemical plant by A.R. Eames
AHSB(S) R131	1967	A method of measuring equipment response time by A.R. Eames
AHSB(S) R136	1967	Safety assessment – a method for determining the performance of alarm and shutdown systems for chemical plants by G. Hensley
AHSB(S) R138	1967	Data store requirements arising out of reliability analyses by A.R. Eames
AHSB(S) R160	1969	A quantitative approach to the evaluation of the safety function of operators on nuclear reactors by J.F. Ablitt
AHSB(S) R162	1968	A survey of defects in pressure vessels built to high standards of construction and its relevance to nuclear primary circuit envelopes by C.A.G. Phillips and R.G. Warwick
AHSB(S) R164	1969	Reliability prediction by AE. Green
AHSB(S) R172	1969	Safety assessment of automatic and manual protective systems for reactors by A.E. Green
AHSB(S) R178	1969	The reliability prediction of mechanical instrumentation equipment for process control by G. Hensley
AHSB(S) R179	1970	Confidence limits for numbers from 0 to 1200 based on the Poisson distribution by E.R. Woodcock and A.R. Eames

SRS/GR series

SRS/GR/1	1973	Plant and process reliability by G. Hensley
SRS/GR/2	1971	Quantitative assessments of system reliability by A.E. Green
SRS/GR/4	1971	Considerations in the use of system reliability models by A.J. Bourne
SRS/GR/9	1971	Human factors by B. Sayers
SRS/GR/12	1973	The effect of equipment reliability upon plant and system performance by A.R. Eames
SRS/GR/13	1973	Some reliability characteristics for operating plant by A.R. Eames and C.D.H. Fothergffl
SRS/GR/14	1973	An introduction to the 'Syrel' data bank by J.F. Ablitt
SRS/GR/22	1973	The analysis and presentation of derived reliability data from a computerised data store by C. Fothergiffl

NCSR series

NCSR R6	1975	Application of diakoptical analysis in system reliability assessment
NCSR R7	1975	Reliability analysis – a systematic approach based on limited data by A.J. Bourne

NCSR R8	1976	Report on the work and activities of the plant availability study group
NCSR RIO	1976	Human reliability in complex systems: an overview by D.E. Embrey
NCSR R11	1977	The effect of operational loading on the failure characteristics of mechanical valves by T.R. Moss
NCSR R12	1976	Advances in Reliability Technology, ed. by T.R. Moss
NCSR R14	1977	The reliability analysis of logical networks by the computer program ALMONA by P. Brock
NCSR 16	1979	A literature survey of computer software reliability by B.K. Daniels and M. Hughes
NCSR 17	1979	Reliability and protection against failure in computer systems by B.K Daniels
NCSR 21	1979	Optimal equipment replacement policies by R.F. de la Mare
NCSR/GR/65	1987	The achievement and assessment of safety in nuclear power reactor systems containing software by C.J. Dale, A. Ball and M.H. Butterfield
NCSR/GR/68	1987	System unavailability for a continuous process having batched input or output by K. Evans
NCSR/GR/71	1987	Performance of pipework in the British sector of the North Sea by AG. Cannon and R.C.E. Lewis

UK Atomic Energy Authority, Safety and Reliability Directorate

(Risley, near Warrington)

SRD Rl	1971	Principles of reliability of nuclear reactor control and instrumentation systems by A.R. Eames
SRD R8	1974	Chemical plants and laboratories safety assessment by A. Fairbairn, E.S. London, L.E. Lockett and A Cook, 1974
SRD R16	1973	Accident probability reduction by the application of service reliability data by J.F. Ablitt
SRD R21	1973	Stress concentration theory of fracture and its relationship to linear elastic fracture mechanics by W.H. Irvine
SRD R26	1974	A stress concentration theory of fracture and its application to various crack geometries by W.H. Irvine
SRD R30	1974	The second survey of defects in pressure vessels built to high standards of construction and its relevance to nuclear primary circuits by T.A Smith and R.G. Warwick
SRD R48	1977	An elasto-plastic theory of fracture and its application to the analysis of experimental data by W.H. Irvine
SRD R57	1976	An appraisal of the PREP KITT and SAMPLE computer codes for the evaluation of the reliability characteristics of engineered systems by P. Shaw and R.F. White
SRD R63	1976	A description of the mathematical and physical models incorporated in TIRION 2 – a computer program that calculates the consequences of a release of radioactive material to the atmosphere and an example of its use by G.D. Kaiser
SRD R67	1977	Critical review of the USCG report by Raj *et al.* (1974) on spills of liquid anhydrous ammonia on to water, with an alternative assessment of the experimental results by R.F. Griffiths
SRD R68	1976	Accident rates from plant failure at high demand frequencies by D.H. Worledge
SRD R80	1977	The use and interpretation of confidence and tolerance intervals in safety analysis by G.W. Parry, P. Shaw and D.H. Worledge
SRD R85	1977	Effect of duration of release on the dispersion of effluent released to the atmosphere by R.F. Griffiths
SRD R91	1978	A method for analysing cargo protection afforded by ship structures in collision and its application to an LNG carrier by A.N. Kinkead
SRD R95	1977	The use of regeneration diagrams to solve component reliability problems by G.W. Parry and D.H. Worledge
SRD R97	1978	HUBBLE-BUBBLE 1: a computer program for the analysis of non-equilibrium flows of water by D.J. Mather
SRD R100	1978	Evaporation from spills of hazardous liquids on land and water by P. Shaw and F. Briscoe
SRD R103	1978	The density of an ammonia cloud in the early stages of dispersion by S.R. Haddock and R.J. Williams

SRD R110	1978	The incidence of multiple fatality accidents in the UK by R.F. Griffiths and L.S. Fryer
SRD R113	1978	The downtime distribution in reliability engineering by G.W. Parry and D.H. Worledge
SRD R118	1978	HUBBLE-BUBBLE II: a computer program to describe non-equilibrium flow of water in simple pipe systems by D. Martin
SRD R125	1978	Individual risk – a compilation of recent British data by D.R. Grist
SRD R128	1979	The role of event trees inreactor accident analysis by D.H. Worledge
SRD R129	1979	The tolerance–confidence relationship and safety analysis by G.W. Parry, P. Shaw and D.H. Worledge
SRD R131	1978	LNG/water vapour explosions – estimates of pressure and yields by F. Briscoe and G.J. Vaughan
SRD R134	1978	TIRION 4: a computer program for use in nuclear safety studies by L.S. Fryer and G.D. Kaiser
SRD R135	1979	A method for the estimation of the probability of damage due to earthquakes by M.A.H.G. Alderson
SRD R143	1979	Regeneration diagrams by G.W. Parry
SRD R146	1979	A study of common-mode failures by G.T. Edwards and I.A. Watson, 1979
SRD R149	1979	World-wide data on the incidence of multiple fatality accidents by L.S. Fryer and R.F. Griffiths
SRD R150	1979	Examples of the successful application of a simple model for the atmospheric dispersion of dense, cold vapours to the accidental release of anhydrous ammonia from pressurised containers by G.D. Kaiser
SRD R152	1979	DENZ – a computer program for the calculation of the dispersion of dense toxic or explosive gases in the atmosphere by L.S. Fryer and G.D. Kaiser
SRD R154	1979	The accidental release of anhydrous ammonia to the atmosphere – a systematic study of factors influencing cloud density and dispersion by R.F. Griffiths and G.D. Kaiser
SRD R155	*c.*1979	Validation of BK WAVE: a computer program for the calculation of one-dimensional shock wave propagation from explosions by F. Briscoe
SRD R173	1983	GASEX2: a two dimensional hydrodynamic code for use in gas cloud explosion calculations by D. Martin
SRD R177	1980	The metal/water explosion phenomenon – a review of present understanding by G.J. Vaughan
SRD R190	1980	The characterisation and evaluation of uncertainty in probabilistic risk analysis by G.W. Parry and P.W. Winter
SRD R196	1981	Defences against common-mode failures in redundant systems. A guide for management, designers and operators by A.J. Bourne, G.T. Edwards, D.M. Hunns, D.R. Poulter and I.A. Watson
SRD R198	1981	UK aircraft crash statistics – 1981 revision by D.W. Phillips
SRD R203	1981	A survey of defects in pressure vessels in the UK for the period 1962–1978 and its relevance to nuclear primary circuits by T.A. Smith and R.G. Warwick
SRD R210	1981	A users manual to SPILL by A.J. Prince, 1981
SRD R217	1982	Matching the results of a theoretical model with failure rates obtained from a population of non-nuclear pressure vessels by L.P. Harrop
SRD R221	1982	A survey of turbulence models with particular reference to dense gas dispersion by C.L. Farmer
SRD R229	1983	Development of CRUNCH: a dispersion model for continuous releases of a denser-than-air vapour into the atmosphere by S.F. Jagger
SRD R238	1982	The transition from pressure-energy to gravity-driven slumping during the catastrophic release of a denser-than-air gas by S.F. Jagger
SRD R240	1983	The thermal response of tanks engulfed in fire by D.L.M. Hunt, P. Ramskill, C.G. Shepherd and R. Young, 1983
SRD R241	1983	A guide to the use of a computer program to model the thermal response of a tank engulfed in fire by P.K. Ramskill, 1983
SRD R243	1983	The physics of heavy gas cloud dispersal by D.M. Webber

SRD R245	1983	Noncoherent structure theory: a review and its role in fault tree analysis by B.D. Johnston and R.H. Matthews
SRD R246	1982	Seismic design criteria and their applicability to major hazard plant within the United Kingdom by M.A.H.G. Alderson
SRD R251	1983	GASEX1 – a general one-dimensional code for gas cloud explosions by J. MacKenzie and D. Martin, 1983
SRD R252	1983	Validation calculations for the code GASEX2 by D. Martin
SRD R254	1984	A suggested method for the treatment of human error in the assessment of major hazards by R.F. White
SRD R262	1983	A computational survey of the factors influencing the pressure fields produced by unconfined vapour cloud by J. MacKenzie
SRD R263	1983	The fire hazards and counter measures for the protection of pressurized liquid petroleum gas storage on industrial sites by KW. Blything
SRD R273	1983	A method of risk assessment for a multi-plant site by R.F. White
SRD R275	1983	The physiological and pathological effects of thermal radiation by I. Hymes
SRD R276	1984	A literature review of fire modelling techniques and related subjects by I.C. Simpson and N.A. Taylor
SRD R277	1985	Application of the computer code DENZ by S.F. Jagger
SRD R292	1984	Fire/explosion probabilities on liquid gas ships by K.W. Blything and J.N. Edmondson
SRD R295	1984	Preliminary studies for the analysis of blast loaded cantilever tests by J. Jowett
SRD R297	1984	Thermal radiation hazard ranges from large hydrocarbon pool fires by M. Considine
SRD R299	1984	FIRENET – a program for performing probabilistic risk assessment of fires in buildings by S.F. Hall and W.M. Scattergood
SRD R300	*c.* 1984	MULTIPLET – a program for calculating large event trees by S.F. Hall
SRD R301	1984	An introduction to fuzzy set theory with a view to the quantification and propagation of vagueness in probabilistic risk and reliability assessment by S.D. Unwin
SRD R302	1985	A study of axisymmetric under-expanded gas jets by P.K. Ramskffl
SRD R303	1984	A study of axi-symmetric two-phase flashing jets by P.R. Appleton
SRD R304	1984	Atmospheric transmissivity – the effects of atmospheric attenuation on thermal radiation by I.C. Simpson
SRD R307	*c.*1984	A modelling study of elevated plumes at a coastal location during onshore flow by P.J. Cooper and W. Nixon
SRD R310	1984	The assessment of individual and societal risks by M. Considine
SRD R314	1986	Analysis of 100 te propane storage vessel by T.A. Smith
SRD R315	1984	A simple parametric model for the dispersion of dense flammable gases by G.C. Grint
SRD R318	1985	Thorney Island heavy gas dispersion trials – determination of path and area of cloud from photographs by A.J. Prince, D.M. Webber and P.W.M. Brighton
SRD R319	*c.*1985	Using concentration data to track clouds in the Thorney Island experiments by P.W.M. Brighton
SRD R324	1985	Details and results of spill experiments of cryogenic liquids on to land and water by A.J. Prince
SRD R325	*c.*1985	Factors influencing pool fires on porous ground by D.M. Webber
SRD R326	1984	In-service reliability data for underground cross-country oil pipelines by K.W. Blything
SRD R327	1985	A model of aerosol deposition in the lung for use in inhalation dose experiments by W. Nixon
SRD R338	1987	The assessment of site-specific aircraft crash hazards by T.M. Roberts
SRD R340	1985	Incident probabilities in liquid gas ships by K.W. Blything and R.C.E. Lewis
SRD R341	*c.*1985	The estimation of missile velocities following the failure of a vessel containing high temperature pressurised water by D.LM. Hunt and AJ. Wood
SRD R342	1985	Cargo protection afforded by hull structure of LPG carriers during grounding at low or drifting speeds by A.N. Kinkead
SRD R347	1985	Guide to reducing human error in process operation (short version) by Human Factors in Reliability Group

SRD R352	1986	Discharge rate calculation methods for use in plant safety assessment by P.K. Ramskill
SRD R353	1987	A review of stainless steel component failures by T.A. Smith
SRD R354	1987	A description of ENGULF, a computer code to model thermal response of a tank engulfed in fire by P.K. Ramskill and D.L.M. Hunt
SRD R355	1985	Comparison between data from Thorney Island heavy gas trials and predictions of simple dispersion models by C.J. Wheatley, A.J. Prince and P.W.M. Brighton
SRD R357	1986	A theory of heterogeneous equilibrium between vapour and liquid phases of binary systems and formulae for the partial pressure of $HF + H_2O$ vapour by C.J. Wheatley
SRD R371	1986	Similarity solutions for the spreading of liquid pools by D.M. Webber and P.W.M. Brighton
SRD R372	1986	A description of the two dimensional combustion code FLARE by D. Martin
SRD R373	1986	Some calculations using the two dimensional combustion code FLARE by D. Martin
SRD R375	1987	Evaporation from a plane liquid surface into a turbulent boundary layer by P.W.M. Brighton
SRD R376	1986	Development of a model to predict the blast response of cantilevers by J. Jowett and J.P. Byrne
SRD R377	1986	Further development of a cantilever blast response model by J. Jowett, J.P. Byrne and T. Roberts
SRD R378	1986	The effects of missile impact on thin metal structures by J. Jowett
SRD R379	1986	A review of hazard identification techniques and their application to major accident hazards by S.T. Parry
SRD R382	1986	AEROSIM-S user manual by S.A. Ramsdale
SRD R383	1985	Common cause failure reliability benchmark exercise by B.D. Johnston and J. Crackett
SRD R390	1987	An integral model for spreading vaporising pools derived from shallow-layer equations by D.M. Webber and P.W.M. Brighton
SRD R393	1987	A theoretical study of NH_3 concentrations in moist air arising from accidental releases of liquefied NH_3 using the computer code TRAUMA by C.J. Wheatley
SRD R394	1987	A users guide to TRAUMA, a computer code for assessing the consequences of accidental two-phase releases of NH_3 into moist air by C.J. Wheatley
SRD R396	1988	Thermodynamics of mixing and final state of a mixture formed by the dilution of anhydrous hydrogen fluoride with moist air by P.N. Clough and C.J. Wheatley
SRD R401	1987	AEROSIM-N user manual by S.A. Ramsdale
SRD R404	1988	A model for the evaporation and boiling of liquid pools by D.M. Webber
SRD R407	1986	Experiments on some effects of obstacles on dense gas dispersion by R.E. Britter
SRD R410	1987	Discharge of liquid ammonia into moist atmospheres – a survey of experimental data and model for estimating initial conditions of dispersion by C.J. Wheatley
SRD R411	1986	Common cause failure reliability benchmark exercise. Phase II by J. Crackett
SRD R412	1987	Feasibility study of the assessment of risks involved in the conveyance of explosives by road by H. Chapman and P.L. Holden
SRD R413	1987	A users guide to ENGULF, a computer code to model the thermal response of a tank engulfed in fire by P.K. Ramskill
SRD R414	1987	The development of ENGULF to model a multi-component Liquid in a fire engulfed tank by P.K. Ramskill
SRD R418	1987	SRD Dependent Failures Procedures Guide by P. Humphreys and B.D. Johnston
SRD R421	1987	Heat conduction under a spreading pool by D.M. Webber
SRD R423	1987	Dry deposition to an urban complex by B.Y. Underwood
SRD R428	1988	FPAs Guide on Fire Precautions by G. Burke and M. Finucane
SRD R431	1988	Reliability of fire protection and detection systems by M. Finucane and D. Pinkney

SRD R435	1987	Criteria for the rapid assessment of aircraft crash onto major hazard installations by D.W. Phillips
SRD R437	1987	An integral dynamic turbulence model for heavy gas cloud dispersal close to the source by D.M.Webber and C.J.Wheatley
SRD R438	1987	Comparison and test of models for atmospheric dispersion of continuous releases of chlorine by C.J.Wheatley, B. Crabol, R.J. Carpenter, S.F. Jagger, C. Nussey, R.P. Cleaver, R.D. Fitzpatrick and A.J. Prince
SRD R 439	1987	Guidelines for the design and assessment of concrete structures subject to impact by P. Barr
SRD R441	1988	Pipework failures – a review of the historical incidents by K.W. Blything and S.T. Parry
SRD R442	1998	Dry deposition to vegetated surfaces parametric dependencies by B.Y. Underwood
SRD R 443	1987	Likelihood as a measure of uncertainty in system reliability and probabilistic safety assessment by A.R. Garlick
SRD R444	1990	Similarity solutions for two dimensional steady gravity currents by P.W.M. Brighton
SRD R455	1987	The application of quality assurance within the UKAEA by F. Allen and T.H. Nixon
SRD R467	1989	Pressures produced by instantaneous chlorine releases inside buildings by P.W.M. Brighton
SRD R468	1989	Continuous chlorine releases inside buildings: concentrations by P.W.M. Brighton
SRD R474	1988	Transport accident frequency data, their sources and their application in risk assessment by P.R. Appleton
SRD R477	1988	Assessment of missile hazards: review of incident experience relevant to major hazard plant by P.L. Holden
SRD R480	1989	ENGULF II: a computer code to model the thermal response of a tank partially or totally engulfed in fire by P.K. Ramskffl
SRD R481	1989	A user's guide to ENGULF II: a computer code to model the thermal response of a tank partially or totally engulfed in fire by P.K. Ramskill and C. Marriott
SRD R483	1989	On the interpretation of puff-trajectory modelling by B.Y. Underwood
SRD R488	1988	An initial prediction of the BLEVE frequency of a 100 te butane storage vessel by K.W. Blything and A.B. Reeves
SRD R492	1988	The predicted BLEVE frequency of a selected 2000 m^3 butane – sphere on a refinery site by M. Selway
SRD R494	1989	Generalisation of the two-phase jet model TRAUMA to substances other than ammonia by D.N.Webber and P.W.M. Brighton
SRD R495	1989	TRAUMA issue 3.5, a users update by S.C. Rutherford and D.M.Webber
SRD R500	1990	The design of bunds by D.S. Barnes
SRD R504	1989	Risk assessment of majorhazards. A brief overview of methods and information sources by P.L. Holden
SRD R507	1990	A model for pool spreading and vaporisation and its implementation in the computer code GASP by D.M.Webber
SRD R509	1990	The long term contribution to severe accident source terms and their mitigation by J.R. Mullins and P.N. Clough
SRD R510	1990	Human error in risk assessment by J. Brazendale
SRD R521	1989	A users guide to G*A*S*P* on microcomputers by D.M.Webber and S.J. Jones
SRD R530	1991	Bund overtopping – the consequences following catastrophic failure of large volume liquid storage vessels by A.Wilkinson
SRD R536	1990	Investigation into the ignition and melting characteristics of apparel fabrics subjected to a radiative heat flux by W. Boydell
SRD R552	1993	A differential phase equilibrium model for clouds, plumes and jets by D.M.Webber and T.Wren
SRD R553	1992	Description of ambient atmospheric conditions for the computer code DRIFT by A.J. Byrne, S.J. Jones, S.C. Rutherford, C.A. Tickle and D.M.Webber
SRD R563	1992	Review of experimental data for validation of the code DRIFT by P.L. Edwards

SRD R578	1992	The probability of fires in warehouses and storages by I. Hymes and J.F. Flynn
SRD R579	1992	Probabilistic risk assessment of radio frequency ignition by P.J. Harrold
SRD R582	1992	The effects of natural and man-made obstacles on heavy gas dispersion. Pt II, Dense gas dispersion over complex terrain by S.J. Jones, D. Martin, D.M. Webber and T. Wren
SRD R583	1992	The effects of natural and man-made obstacles on heavy gas dispersion – report summary by P.W.M. Brighton, S.J. Jones, D. Martin, D.M. Webber and T. Wren
SRD R584	1992	Mathematical modelling of two phase release phenomena in hazard analysis by D.M. Webber, G.A. Tickle, T. Wren and J. Kukkonen
SRD R585	1992	Mathematical modelling of two phase release phenomena in hazard analysis – report summary by D.M. Webber, G.A. Tickle, T. Wren and J. Kukkonen
SRD R 586	1992	A model of a dispersing dense gas cloud and the computer implementation DRIFT I. Instantaneous releases by D.M. Webber, S.J. Jones, G.A. Tickel and T. Wren
SRD R 587	1992	A model of a dispersing dense gas cloud and the computer implementation DRIFT II. Steady continuous releases by D.M. Webber, S.J. Jones, G.A. Tickel and T. Wren
SRD R552	1993	A differential phase equilibrium model for clouds, plumes and jets by D.M. Webber and T. Wren
SRDA R1	1991	Developing best operating procedures by Bardsley and Jenkins
SRDA R3	1991	The guide to reducing human error in process operation by P. Ball

Welding Institute

Weldability of Steel by K.G. Richards, 1967	1
Weld Preparations for Fusion Welding of Steelby K.G. Richards, 1966	2
Fatigue of Welded Structures,1969	3
Heat Treatment of Welded Structures, 2nd ed., by F.M. Burdekin, 1969	4
Welding Dissimilar Metals, 1969	5
CO_2 Welding, 3rd ed., by A.A. Smith, 1970	6
Pipe Welding, 1970	7
Welding Cast Austenitic Steels, 1970	8
Welding Creep Resistant Steels, 1970	9
Welding Procedures for Low Alloy Steels by N. Bailey, 1970	10
Advances in Welding Processes 1971	11
Brittle Fracture of Welded Structures by K.G. Richards,1971	12
Electron-Beam Welding – Principles and Practice, ed. by A.H. Meleka, 1971 (London: McGraw-Hill)	13
Fatigue of Welded Structures, 1971	14
Procedures and Recommendations for the Ultrasonic Testing of Butt Welds, 2nd ed., 1971	15
Weldability of Structures and Pressure Vessels, 1971	16
Improving Welded Product Design, 1972	17
Lamellar Tearing in Welded Steel Fabrication, 1972	18
NDT Aspects of the Significance of Weld Defects, 1972	19
Pressure Vessel Standards – the Impact of Change, 1972	20
Welding and Fabrication of Non-Ferrous Metals, 1972	21
Fatigue Performance of Welded High Strength Steels, 1973	22
Handbook of Radiographic Apparatus and Techniques, 1973	23
Surface Coatings for Savings in Engineering, 1973	24
Welding Steel without Hydrogen Cracking, 1973	25
Advances in Welding Processes, 1974	26
Quality Control and Non-Destructive Testing in Welding, 1974	27
Welding Low Temperature Containment Plant, 1974	28
Standard Data for Arc Welding, 1975	29
The Toughness of Weld Heat Affected Zones, 1975	30
Weld Decay in Austenitic Stainless Steel by T.G. Gooch and D.C. Willingham, 1975	31
Welding Processes – Engineering Design Guide by P.T. Houldcroft, 1975 (Oxford: Oxford Univ. Press)	32
Recommendations for Friction Welding of Butt Joints in Metals for High Duty Applications,1975	33
Control of Distortion in Welded Fabrication, 2nd ed., 1976	34
The Present Position Concerning the Biological Effects of Exposure to Fume in Welders by M.L Newhouse and R. Murray, 1981	35
Welding Fume – Sources, Characteristics and Control by N. Jenkins, J. Moreton, P.J. Oakley and S.M. Stevens, vols 1–2, 1981–	36
Guidelines for Fracture-Safe and Fatigue-Reliable Design of Steel Structure by W.S. Pellini, 1983	37
The Facts about Fume, 2nd ed., ed. by N. Jenkins, 1986	38
Introduction to the Non-Destructive Testing of Welded Joints by R. Halmshaw, 1988	39
A Guide to Designing Welds by J. Hicks, 1989	40
Weld Failures ed. by J. Harrison, 1989	41
Fatigue Strength of Welded Structures, 2nd ed., by S.J. Maddox, 1991	42
Health and Safety in Welding and Allied Processes, 4th ed., ed. by N.C. Balchin, 1991	43
Process Pipe and Tube Welding ed. by W. Lucas, 1991	44
Welding Structural and Corrosion Resistant Materials by J.F. Lancaster, 1992	45

World Health Organisation

(Geneva)

Environmental Health Criteria

EHC1	Mercury
EHC2	polychlorinated Biphenyls and Terphenyls
EHC3	Lead
EHC4	Oxides of Nitrogen
EHC5	Nitrates, Nitrites and N-Nitroso Compounds
EHC6	Principles and Methods for Evaluating the Toxicity of Chemicals, Pt 1
EHC7	Photochemical Oxidants
EHC8	Sulphur Oxides and Suspended Particulate Matter
EHC9	DDT and its Derivatives
EHC10	Carbon Disulphide
EHC12	Noise
EHC13	Carbon Monoxide
EHC14	Ultraviolet Radiation
EHC19	Hydrogen Sufflde, 1983
EHC20	Selected Petroleum Products
EHC21	Chlorine and Hydrogen Chloride
EHC28	Acrylonitrile
EHC53	Asbestos
ECH54	Ammonia

Note:
Some of the series in this appendix which are shown with a closed range of dates are continuing series, e.g. the AlChE series on Ammonia Plant Safety

B Nuclear Regulatory Commission

Periodic Reports

NUREG-0020	Licensed operators reactor status summary
NUREG-0040	Licensee contractor and vendor inspection status report
NUREG-0090	Report to Congress on abnormal occurrences
NUREG-0304	Regulatory and technical reports (abstract index journal)
NUREG-0525	Safeguards summary event list
NUREG-0540	Title list of documents made publicly available
NUREG-0750	Indexes to nuclear regulatory commission issuances
NUREG-0933	A prioritization of generic safety issues
NUREG-0936	NRC regulatory agenda
NUREG-0940	Enforcement actions: significant actions resolved
NUREG-1125	A compilation of reports of the Advisory Committee on Reactor Safeguards
NUREG-1145	US Nuclear Regulatory Commission annual report
NUREG-1214	Historical data summary of the systematic assessment of licensee performance
NUREG-1415	Office of the Inspector General. Semi-annual Report

Acoustic Emission Monitoring

NUREG/CR-3825:1985	Acoustic emission/flaw relationship for in-service monitoring of nuclear pressure vessels
NUREG/CR-4300:1985–	Acoustic emission/flaw relationship for in-service monitoring of nuclear pressure vessels. Also 1986, 1987
NUREG/CR-5645:1991	Acoustic emission/flaw relationships for in-service monitoring of LWRs

Aerosols

NUREG/CR-1367: 1981	AEROSOL user's manual
NUREG/CR-2139: 1981	Aerosols generated by free fall of powders and solutions in static air
NUREG/CR-2299: 1982	Aerosol release and transport program
NUREG/CR-3422:1984	Aerosol release and transport program
NUREG/CR-3830:1985	Aerosol release and transport program
NUREG/CR-4342:1985	Uncertainty and sensitivity analysis of a model for multicomponent aerosol dynamics
NUREG/CR-4501:1986	Modeling of vapor generation in flashing flow
NUREG/CR-4658:1986	Aerosols generated by spills of viscous solutions and slurries
NUREG/CR-4779:1987	New data for aerosols generated by releases of pressurized powders and solutions in static air
NUREG/CR-4997:1988	Methods for describing air-borne fractions of free fall spills of powders and liquids
NUREG/CR-5162:1988	CHARM: a model for aerosol behaviour in time varying thermal–hydraulic conditions

Aging

NUREG/CR-3156:1983	A survey of state-of-the-art in aging of electronics with application to nuclear power plant instrumentation
NUREG/CR-3808:1984	Aging–seismic correlation study on class IE equipment
NUREG-1144:1985	Nuclear plant aging research (NPAR) program plan
NUREG/CR-3819:1985	Survey of aged power plant facilities
NUREG/CR-4144:1985	Importance ranking based on aging considerations of components included in probabilistic risk assessments
NUREG/CR-4156:1985	Operating experience and aging–seismic assessment of electric motors
NUREG/CR-4234:1985	Aging and service wear of electric motor-operated valves used in engineered safety-feature systems of nuclear power plants
NUREG/CR-4279:1986	Aging and service wear of hydraulic and mechanical snubbers used in safety-related piping and components of nuclear power plants

NUREG/CR-4548:1986	Correlation of electrical reactor cable failure with materials degradation
NUREG/CR-4597:1986	Aging and service wear of auxiliary feedwater pumps for PWR nuclear power plants
NUREG-1144:1987	Nuclear plant aging research (NPAR) program plan
NUREG/CR-4590:1987	Aging of nuclear station diesel generators
NUREG/CR-4715:1987	An aging assessment of relays and circuit breakers and system, interactions
NUREG/CR-4731:1987	Residual life assessment of major light water reactor components
NUREG/CR-4769:1987	Risk evaluations of aging phenomena
NUREG/CR-4928:1987	Degradation of nuclear plant temperature sensors
NUREG/CR-4747:1988	An aging failure survey of light water reactor safety systems and components
NUREG/CR-4992:1988	Aging and service wear of multistage switches used in safety systems of nuclear power plants
NUREG/CR-5057:1989	Aging mitigation and improved programs for nuclear service diesel generators
NUREG/CR-5314:1990	Life assessment procedures for major LWR components
NUREG/CR-5419:1990	Aging assessment of instrument air systems in nuclear power plants
NUREG/CP-4302: 1991	Aging and service wear of check valves used in engineered safety feature systems of nuclear power plants

Alcohol, Drug Abuse

NUREG-0903: 1982	Survey of industry and government programs to combat drug and alcohol abuse
NUREG/CR-3196:1983	Drug and alcohol abuse: the bases for employee assistance programs in the nuclear utility industry
NUREG/CR-5784:1991	Fitness for duty in the nuclear power industry

Auxiliary Feedwater System

NUREG/CR-5404:1990	Auxiliary feedwater system aging

Bolts

NUREG-1339:1990	Resolution of generic safety issue 29: bolting degradation or failure in nuclear power plants

Chernobyl

NUREG-1250:1987	Report on the accident at the Chernobyl nuclear power station
NUREG-1251:1987	Implications of the accident at Chernobyl for safety regulation of commercial nuclear power plants in the United States (draft)
NUREG-1251:1989	Implications of the accident at Chernobyl for safety regulation of commercial nuclear power plants in the United Sates

Combustion

NUREG/CR-2658:1983	Characteristics of combustion products: a review of the literature
NUREG/CR-4855:1987	Development and application of a computer model for large-scale flame acceleration experiments
NUREG/CR-5275:1989	Flame facility: the effect of obstacles and transverse venting on flame acceleration and transition for hydrogen-air mixtures

Common Cause Failure

NUREG/CR-2099:1982	Common cause fault rates for diesel generators: estimates based on Licensee Event Reports at US commercial nuclear power plants
NUREG/CR-2098:1983	Common cause fault rates for pumps: estimates based on Licensee Event Reports at US commercial nuclear power plants
NUREG/CR-2770:1983	Common cause fault rates for valves
NUREG/CR-2771:1983	Common cause fault rates for instrumentation and control assemblies
NUREG/CR-3289:1983	Common cause fault rates for instrumentation and control assemblies
NUREG/CR-3437:1983	Data analysis using binomial failure rate common cause model
NUREG/CR-4314:1985	Brief survey and comparison of common cause failure analysis
NUREG/CR-4780:1988	Procedures for treating common cause failures in safety and reliability studies
NUREG/CR-5044:1988	Estimation techniques for common cause failure events
NUREG/CR-4780:1989	Procedures for treating common cause failures in safety and reliability studies
NUREG/CR-5460:1990	A cause-defense approach to the understanding and analysis of common cause failures

Computer Reliability

NUREG/CR-2118:1981	Reactor safety system design using hardened computers
NUREG/CR-2288:1982	Computer surety
NUREG/CR-3360:1984	Computer program CDCID, an automated quality control program using CDC update

Computer Software Reliability

NUREG/CR-2186:1982	Quantitative software reliability analysis of computer codes relevant to nuclear safety
NUREG/CR-4369:1986	Quality assurance (QA) plan for computer software supporting the US Nuclear Regulatory Commission's high-level waste program
NUREG/CR-4640:1987	Handbook of software quality assurance techniques applicable to the nuclear industry

Containment

NUREG/CP-0033:1982	Proceedings of the workshop on Containment Integrity
NUREG/CR-3855:1985	Characterization of nuclear reactor containment penetration
NUREG/CR-4119:1985	Integrity of containment penetrations under severe accident conditions
NUREG/CR-4149:1985	Ultimate pressure capacity of reinforced and prestressed concrete containment
NUREG/CR-4220:1985	Reliability analysis of containment isolation systems
NUREG/CR-5096:1988	Evaluation of seals for mechanical penetrations of containment buildings
NUREG/CR-5394:1989	Evaluation of the leakage behavior of inflatable seals subject to severe accident conditions
NUREG/CR-5602:1990	Simplified containment event tree analysis for the Sequoyah ice condenser containment

Control System, Including Displays, Alarms, Computers, Computer Aids

NUREG/CR-2776:1982	Alarms within advanced display systems: alternatives and performance measures
NUREG/CR-2988:1982	An approach to modeling supervisory control of a nuclear power plant
NUREG/CR-3461:1984	Response tree evaluations – implications for the use of artificial intelligence in process control rooms
NUREG/CR-3621:1984	Safety system status monitoring
NUREG/CR-3631:1984	Response trees and expert systems for nuclear reactor operators
NUREG/CR-3655:1984	A method for analytical evaluation of computer-based decision aids
NUREG/CR-4017:1984	Interim criteria for the use of programmable digital devices in safety and control systems
NUREG/CR-3987:1985	Computerized annunciator systems
NUREG/CR-4227:1985	Human engineering guidelines for the evaluation and assessment of video display units
NUREG/CR-4272:1985	Response tree evaluation: experimental assessment of an expert system for nuclear reactor operators
NUREG/CR-3958:1986	Effects of control system failures on transients, accidents and core-melt frequencies at Combustion Engineering pressurized water reactor
NUREG/CR-4463:1986	Human factors in annunciator/alarm systems: annunciator experiment plan I
NUREG/CR-4577:1987	Automated long-term surveillance of a commercial nuclear power plant
NUREG/CR-4797:1987	Progress reviews of six safety parameter display systems
NUREG/CR-5011:1987	Application of the adaptive-predictive controllers to plant safety surveillance utilizing online plant analyzer
NUREG-1217:1988	Evaluation of safety implications of control systems in LWR nuclear power plants (draft)
NUREG-1217:1989	Evaluation of safety implications of control systems in LWR nuclear power plants (draft)
NUREG-1342:1989	A status report regarding industry implementation of safety parameter display
NUREG-1361:1989	Lessons learned in process control at the Halden reactor project

Control Room Design

NUREG-0700:1981	Guidelines for control room design reviews
NUREG-0801:1981	Evaluation criteria for detailed control room design review
NUREG/CR-3696:1984	Potential human factors deficiencies in the design of local control stations and operator interfaces in nuclear power plants
NUREG/CR-3975:1984	Identification and assessment of anticipated major changes in control rooms
NUREG/CR-4191:1985	Survey of licensee control room habitability practices

NUREG/CR-5659:1990	Control room habitability system review models

Corrosion

NUREG/CR-2541:1982	Environmentally assisted cracking in light water reactors: critical issues and recommended research
NUREG/CR-3220:1983	Mechanistic aspects of stress-corrosion cracking of type 304 stainless steel in LWR systems
NUREG/CR-3806:1984	Environmentally assisted cracking in light water reactors
NUREG/CR-4221:1985	An evaluation of stress corrosion crack growth in BWR piping systems
NUREG/CR-4287:1985	Environmentally assisted cracking in light water reactors
NUREG/CR-4464:1986	Performance demonstration tests for detection of intergranular stress corrosion cracking
NUREG/CR-4667:1986	Environmentally assisted cracking in light water reactors
NUREG/CR-4723:1986	Application of a two-mechanism model for environmentally-assisted crack growth
NUREG/CR-5007:1987	Prediction and mitigation of erosive–corrosive wear in secondary piping systems of nuclear power plants
NUREG/CR-5156:1988	Review of erosion–corrosion in single-phase flows
NUREG-1343:1989	Erosion/corrosion-induced pipe wall thinning in US nuclear power plants

Cost Estimation

NUREG/CR-3971:1984	A handbook for cost estimating
NUREG/CR-4568:1986	A handbook for quick estimates
NUREG/CR-4627:1986	Generic cost estimates

Crack Growth, Fatigue, Fracture Mechanics

NUREG/CR-2301:1982	Fracture mechanics models developed for piping reliability assessment in light water reactors
NUREG/CR-2467:1982	Lower bound KI_{scc} values for bolting materials – a literature study
NUREG/CP-0051:1984	Proceedings of the CSNI specialist meeting on Leak-before-Break in Nuclear Reactor Piping
NUREG/CR-3644:1984	Review of proposed failure criteria for ductile materials
NUREG/CR-3982:1984	Case study of the propagation of a small flaw under PWR loading conditions and comparison with the ASME code design life
NUREG/CR-3723:1985	Stress–intensity-factor influence coefficients for surface flaws in pressure vessels
NUREG/CR-3945:1985	Fatigue crack growth rates of low-carbon and stainless steel piping steels in PWR environments
NUREG/CR-4305:1985	Comments on the leak-before-break concept for nuclear power plant piping systems
NUREG/CR-4325:1985	A parametric study of PWR pressure vessel integrity during overcooling incidents, considering both 2-D and 3-D flaws
NUREG/CR-4422:1985	A review of the models and mechanisms for environmentally-assisted crack growth of pressure vessel and piping steels in PWR environments
NUREG/CP-0067:1986	Proceedings of the second IAEA specialists meeting on Subcritical Crack Growth
NUREG/CP-0077:1986	Proceedings of the seminar on Leak-before-Break
NUREG/CR-4538:1986	Fracture analysis of welded type 304 stainless steel pipe
NUREG/CR-4806:1986	Analysis of cracks in stainless steel TIG welds
NUREG/CR-4724:1987	Fatigue crack growth rates in pressure vessel and piping steels in LWR environments
NUREG/CR-4841:1987	Fracture evaluation of surface cracks embedded in reactor vessel cladding
NUREG/CR-4853:1987	Approximate methods for fracture analysis of through-wall cracked pipe
NUREG/CP-0092:1988	Proceedings of the seminar on Leak-before-Break
NUREG/CR-4828:1988	Fatigue crack growth of part-through cracks in pressure vessel and piping steels
NUREG/CR-4667:1989	Environmentally assisted cracking in light water reactors
NUREG/CP-0109:1990	Proceedings of the seminar on Leak-before-Break
NUREG/CP-0037	Proceedings of the seminar on Assessment of Fracture Prediction Technology: Piping and Pressure Vessels

Data Fitting

NUREG-1378:1989	PLOTNFIT: a basic program for data plotting and curve fitting

Diesel Generators

NUREG-0873:1982	A Bayesian analysis of diesel generator failure data
NUREG/CR-4347:1985	Emergency diesel generator operating experience, 1981–1983

NUREG/CR-4557:1986	A review of issues related to improving nuclear power plant diesel generator reliability
NUREG/CR-4810:1987	Evaluation of diesel unavailability and risk effective surveillance test intervals
NUREG/CR-5078:1988	A reliability program for emergency diesel generators at nuclear power plants

Dispersion in Water Courses

NUREG-0868:1982	A collection of mathematical models for dispersion in surface water and groundwater

Eddy Current Inspection

NUREG/CR-2305:1982	Eddy current inspection for steam generator tubing program
NUREG/CR-2824:1983	Eddy-current inspection for steam generator tubing program
NUREG/CR-3200:1983	Eddy current inspection for steam generator tubing program: quarterly progress report
NUREG/CR-2824:1984	Eddy-current inspection for steam generator tubing program (progress report)
NUREG/CR-3949:1985	Eddy current inspection for steam generator tubing program

Electric Motors

NUREG/CR-4939:1988	Improving motor reliability in nuclear power plants

Electrical Systems

NUREG/CR-2559:1982	Results of phase one of plant electrical system (PES) study
NUREG/CR-3063:1983	A summary of the plant electrical systems (PES) study
NUREG/CR-3122:1983	Potential damaging failure modes of high- and medium-voltage electrical equipment
NUREG/CR-3623:1984	Status report: correlation of electrical cable failure with mechanical degradation
NUREG/CR-4257:1986	Inspection, surveillance and monitoring of electrical equipment in nuclear power plants

Emergency Procedures

NUREG-0696:1981	Functional criteria for emergency response facilities
NUREG-0799:1981	Criteria for preparation of emergency operating procedures (draft)
NUREG/CR-1970:1981	Development of a checklist for evaluating emergency procedures used in nuclear power plants
NUREG/CR-1977:1981	Guidelines for preparing emergency procedures for nuclear power plants
NUREG/CR-1999:1981	Human engineering guidelines for use in preparing emergency operating procedures for nuclear power plants
NUREG/CR-2005:1981	Checklist for evaluating emergency operating procedures used in nuclear power plants
NUREG-0899:1982	Guidelines for the preparation of emergency operating procedures
NUREG/CR-2005:1983	Checklist for evaluating emergency operating procedures used in nuclear power plants
NUREG/CR-3177:1983	Methods for review and evaluation of emergency procedure guidelines
NUREG/CR-3632:1984	Methods for implementing revisions to emergency operating procedures
NUREG-1210:1987	Pilot program: NRC severe reactor accident incident response training manual
NUREG-1358:1989	Lessons learned from the special inspection program for emergency operating procedures
NUREG/CR-5228:1989	Techniques for preparing flow chart-format emergency operating procedures

Emergency Response, Emergency Planning

NUREG-0755:1981	Report to Congress on status of emergency response planning for nuclear power plants
NUREG-0814:1981	Methodology for evaluation of emergency response facilities
NUREG/CP-0032:1982	Workshop on Meteorological Aspects of Emergency Response Plans for Nuclear Power Plants
NUREG/CR-2629:1982	Interim source term assumptions for emergency planning and equipment qualification
NUREG/CR-2654:1982	Procedures for analyzing the effectiveness of siren systems for alerting the public
NUREG/CR-2655:1982	Evaluation of the prompt alerting systems at four nuclear power stations
NUREG/CR-2925:1983	In-plant considerations for optimal offsite response to reactor accidents
NUREG/CR-3524:1984	Organizational interface in reactor emergency planning and response

NUREG/CR-4093:1985	Safety/safeguards interactions during safety-related emergencies at nuclear power reactor facilities
NUREG/CR-4151:1985	Integration of emergency action levels with Combustion Engineering operating procedures
NUREG/CR-4177:1985	Management of severe accidents
NUREG/CR-3365:1986	Report to the NRC on guidance for preparing scenarios for emergency preparedness exercises at nuclear generating stations (draft)
NUREG/CR-5474:1990	Assessment of candidate accident management strategies
NUREG/CR-5513:1990	Accident management information needs
NUREG/CR-5543:1991	A systematic process for developing and assessing accident management plans

Equipment Qualification, Specification

NUREG/CR-4301:1987	Status report on equipment qualification issues research and resolution
NUREG/CR-5012:1988	Similarity principles for equipment qualification by experience
NUREG/CR-5227:1989	Fitness for duty in the nuclear power industry: a review of technical issues
NUREG/CR-5742:1991	Feasibility assessment of a risk-based approach to technical specifications

Error Propagation

NUREG/CR-2839:1983	Survey of error propagation in systems

Evacuation

NUREG/CR-1856:1981	An analysis of evacuation time estimates around 52 nuclear power plant sites
NUREG/CR-2504:1982	CLEAR (calculates logical evacuation and response): a generic transportation network model for the calculation of evacuation time estimates
NUREG/CR-4726:1987	Evaluation of protective action risks
NUREG/CR-4878:1988	The sensitivity of evacuation time estimates to changes in input parameters for the I-DYNEV computer code

Event Trees

NUREG/CR-5174:1989	A reference manual for the event progression analysis code (EVNTRE)

Expert Judgement

NUREG/CR-3115:1983	Expert opinion and ranking methods
NUREG-1290:1987	Differing professional opinions
NUREG/CR-4814:1987	Sources of correlation between experts
NUREG/CR-4962:1987	Methods for the elicitation and use of expert opinion in risk assessment
NUREG-1290:1988	Differing professional opinions
NUREG/CR-5424:1990	Eliciting and analyzing expert judgment

External Hazards

NUREG/CR-1748:1981	Hazards to nuclear power plants from nearby accidents involving hazardous material – preliminary assessment
NUREG/CR-2014:1981	Kinematics of translating tornado wind fields
NUREG/CR-2490:1982	Hazards to nuclear power plants from large liquefied natural gas (LNG) spills on water
NUREG/CR-2555:1982	Data requirements for the evaluation of storm surge models
NUREG/CR-2557:1982	Simulated tornado wind fields and damage patterns
NUREG/CR-2639:1982	Historical extreme winds for the United States-Atlantic and Gulf of Mexico coastlines
NUREG/CR-2678:1982	Flood risk analysis methodology development project
NUREG/CR-2840:1982	Annotated tsunami bibliography
NUREG/CR-2859:1982	Evaluation of aircraft crash hazards for nuclear power plants
NUREG-0965:1983	NRC inventory of dams
NUREG/CR-2462:1983	Capacity of nuclear power plant structures to resist blast loading
NUREG/CR-2879:1983	Feasibility for quantitative assessment of available margins inherent in flood protection of nuclear power plants
NUREG/CR-2944:1983	Tornado damage risk assessment
NUREG/CR-3058:1983	A methodology for tornado hazard probability assessment
NUREG/CR-3060:1983	A critical review of flooding literature
NUREG/CR-3330:1983	Vulnerability of nuclear power plant structures to large external fires
NUREG/CR-3548:1983	Hazardous materials accidents near nuclear power plants: an evaluation of analyses and approaches

NUREG/CR-3670:1984	Violent tornado climatography, 1880–1982
NUREG/CR-3759:1984	Lightning strike density for the contiguous United Sates from thunderstorm duration records
NUREG/CR-3848:1984	Experimental investigation of unsteady tornadic wind loads on structures
NUREG/CR-3874:1984	Near-ground tornado wind fields
NUREG/CR-4250:1985	Vehicle barriers: emphasis on natural features
NUREG/CR-4461:1986	Tornado climatology of the contiguous United States
NUREG/CR-4492:1986	Methodology for estimating extreme winds for probabilistic risk assessments
NUREG/CR-4496:1986	A system for generating long streamflow records for study of floods of long return period
NUREG/CR-5042:1987	Evaluation of external hazards to nuclear power plants in the United States
NUREG/CR-5042:1989	Evaluation of external hazards to nuclear power plants in the United States
NUREG-1407	Procedural and submittal guidance for individual plant examination of external events (PEEE) for severe accident vulnerabilities. Final Report

Failures

NUREG/CR-5611:1991	Issues and approaches for using equipment reliability alert levels
NUREG/CR-5665:1991	A systematic approach to repetitive failures

Failure Data

NUREG/CR-2232:1981	Nuclear plant reliability data system 1980 annual report
NUREG/CR-2641:1982	The in-plant reliability data base for nuclear power plant components
NUREG/CR-3831:1985	The in-plant reliability data base for nuclear plant components
NUREG/CR-4639:1990	Nuclear computerized library for assessing nuclear reactor reliability (NUCLARR)
NUREG/CR-5691:1991	Instrumentation availability for a pressurized water reactor with a large dry containment during severe accidents

Failure Data Analysis

NUREG/CR-2374:1981	Use of non-conjugate prior distributions in compound failure models
NUREG/CR-2375:1981	SAFE-R and SAFE-D: computer codes for the analysis of failure data
NUREG/CR-2434:1982	FRAC (failure rate analysis code): a computer program for analysis of variance of failure rates
NUREG/CR-2464:1982	Methods for classifying mixtures of exponential distributions based on either exponential or Poisson data
NUREG/CR-2465:1982	An error and uncertainty analysis of classical and Bayesian failure rate estimates from a Poisson distribution
NUREG/CR-2714:1982	Analysis of failure rate data with compound models
NUREG/CR-2729:1983	User's guide to BFR: a computer code based on the binomial failure rate common cause model
NUREG/CR-4217:1985	A statistical analysis of nuclear power plant valve failure-rate variability – some preliminary results
NUREG/CR-4616:1987	Root causes of component failures program
NUREG/CR-4672:1987	Analysis of instrument tube ruptures in Westinghouse 4-loop pressurized water reactors

Fans and Blowers

NUREG/CR-4931:1987	Response of centrifugal and axi-vane blowers to large pressure transients

Fault Trees, Fault Tree Analysis

NUREG-0492:1981	Fault tree handbook
NUREG/CR-1965:1981	The use of the computer code IMPORTANCE with SETS input
NUREG/CR-2327:1981	Computation of probabilistic importance measures
NUREG/CR-1935:1982	Quantitative fault tree analysis using the set evaluation program (SEP)
NUREG/CR-3263:1983	A comparison of methods for uncertainty analysis of nuclear power plant safety system fault tree models
NUREG/CR-3268:1983	Modular fault tree analysis procedures guide
NUREG/CR-3134:1984	A SETS user's manual for vital area analysis
NUREG/CR-3547:1984	A SETS user's manual for accident sequence analysis
NUREG/CR-4598:1986	A user's guide for the top event matrix analysis code (TEMAC)
NUREG/CR-4800:1987	SIGPI user's manual for fast computation of probabilistic performance of complex systems
NUREG/CR-5242:1988	A fast bottom-up algorithm for computing the cut sets of noncoherent fault trees

Fire, Fire Protection

NUREG/CR-2258:1981	Fire risk analysis for nuclear power plants
NUREG/CR-2269:1981	Probabilistic models for the behavior of compartment fires
NUREG/CR-2321:1981	Investigation of fire stop test parameters. Final report
NUREG/CR-2377:1982	Tests and criteria for fire protection of cable penetrations
NUREG/CR-2413:1982	Burn mode analysis of horizontal cable tray fires
NUREG/CR-2607:1983	Fire protection research program for the US Nuclear Regulatory Commission 1975–1981
NUREG/CR-3239:1983	COMPBRN – a computer code for modeling compartment fires
NUREG/CR-3385:1983	Measures of risk importance and their applications
NUREG-1148:1985	Nuclear power plant fire protection research program
NUREG/CR-4112:1985	Investigation of cable and cable system fire test parameters
NUREG/CR-4230:1985	Probability-based evaluation of selected fire protection features in nuclear power plants
NUREG/CR-4321:1985	Full scale measurements of smoke transport and deposition in ventilation system ductwork
NUREG/CR-3656:1986	Evaluation of suppression methods for electrical cable fires
NUREG/CR-4310:1986	Investigation of potential fire-related damage to safety-related equipment in nuclear power plants
NUREG/CR-4479:1986	The use of a field model to assess fire behavior in complex nuclear plant
NUREG/CR-4566:1986	COMPBRN II – a computer code for modeling compartment fires
NUREG/CR-4586:1986	User's guide for a personal computer-based nuclear power plant fire data base
NUREG/CR-4596:1986	Screening test of representative nuclear power plant components exposed to secondary environments created by fires
NUREG/CR-4638:1986	Transient fire environment cable damageability test results
NUREG/CR-4527:1987	An experimental investigation of internally ignited fires in nuclear power plant control cabinets
NUREG/CR-4679:1987	Quantitative data on the fire behaviour of combustible materials found in nuclear power plants
NUREG/CR-5088:1989	Fire risk scoping study: investigation of nuclear power plant fire risk, including previously unaddressed issues
NUREG/CR-5384:1989	A summary of nuclear power plant fire safety research at Sandia National Laboratories, 1975–1987

Fluid Flow

NUREG/CR-4766:1987	User's manual for the NEFTRAN computer code
NUREG/CR-5128:1991	Evaluation and refinement of leak-rate estimation models

Gas Dispersion

NUREG/CR-1395:1981	EOCR building wake effects on atmospheric diffusion
NUREG/CR-1473:1981	The wake and diffusion structure behind a model industrial complex
NUREG/CR-2260:1981	Technical basis for Regulatory Guide 1.145 'Atmospheric dispersion models for potential accident consequence assessment at nuclear power plants'
NUREG/CR-2395:1982	Wind tunnel study of gas dispersion near a cubical model building
NUREG/CR-2521:1982	Method for estimating wake flow and effluent dispersion near simple block-like buildings
NUREG/CR-2584:1982	Meteorological considerations in the development of a real-time atmospheric dispersion model for reactor effluent exposure pathway
NUREG/CR-2754:1982	Critical review of studies on atmospheric dispersion in coastal regions
NUREG/CR-2858:1982	PAVAN: an atmospheric dispersion program for evaluating design basis accidental releases of radioactive materials from nuclear power stations
NUREG/CR-3149:1983	Dispersion coefficients for coastal regions
NUREG/CR-3250:1983	Atmospheric transport and diffusion mechanisms in coastal circulation systems
NUREG/CR-3344:1983	MESO I Version 2.0: an interactive mesoscale Lagrangian puff dispersion model with deposition and decay
NUREG/CR-3352:1983	Fumigation potential at inland and coastal power plant sites
NUREG/CR-3368:1983	Diffusion rates for elevated releases
NUREG/CR-3456:1983	Hanford atmospheric dispersion data: 1960 through June 1967

NUREG/CR-3488:1985	Idaho field experiment
NUREG/CR-4072:1985	The estimation of atmospheric dispersion at nuclear power plants utilizing real-time anemometer statistics
NUREG/CR-4157:1985	A scientific critique of available models for real-time simulations of dispersion
NUREG/CR-4158:1985	A compilation of information on uncertainties involved in deposition modeling
NUREG/CR-4159:1985	Comparison of the 1981 INEL dispersion data with results from a number of different models
NUREG/CR-4113:1986	Flow and dispersion near clusters of buildings
NUREG/CR-4222:1986	Analyses of plume formation, aerosol agglomeration and rainout following containment failure
NUREG/CR-4603:1986	Appraising atmospheric transport and diffusion models for emergency response facilities
NUREG/CR-4950:1987	The shoreline environment atmospheric dispersion experiment (SEADEX)
NUREG/CR-4950:1989	The shoreline environment atmospheric dispersion experiment (SEADEX)

Gas Mixing

NUREG/CR-4020:1985	HMS: a computer program for transient, three-dimensional mixing gases

Glossaries

NUREG-0770:1981	Glossary of terms

Human Error

NUREG-CR-1880:1981	Initial quantification of human errors associated with reactor safety system components in licensed nuclear power plants
NUREG/CR-2416:1982	Initial quantification of human error associated with specific instrumentation and control system components in licensed nuclear power plants
NUREG/CR-2417:1982	Identification and analysis of human errors underlying pump and valve related events reported by nuclear power plant licensees
NUREG/CR-2987:1983	Identification and analysis of human errors underlying electrical/electronic component related events reported by nuclear power plant licensees
NUREG/CR-3309:1984	A simulator-based study of human errors in nuclear power plant control room tasks
NUREG/CR-3518:1984	SLIM-MAUD: an approach to assessing human error probabilities using structured expert judgment
NUREG/CR-4436:1986	Human reliability impact on in-service inspection
NUREG/CR-5319:1989	Risk sensitivity to human error

Human Factors

NUREG/CR-1908:1981	Criteria for safety-related nuclear power plant operator actions
NUREG/CR-2075:1981	Standards for psychological assessment of nuclear facility personnel
NUREG/CR-2076:1981	Behavioral reliability program for the nuclear industry
NUREG-0872:1982	Study of using Licensee Event Reports for a statistical assessment of the effect of overtime and shift work on operator error
NUREG/CR-2586:1982	A survey of methods for improving operator acceptance of computerized aids
NUREG/CR-2833:1982	Critical human factors issues in nuclear power regulation and recommended comprehensive human factors long-range plan
NUREG-0985:1983	US Nuclear Regulatory Commission human factors program plan
NUREG-0985:1984	US Nuclear Regulatory Commission human factors program plan
NUREG/CR-3520:1984	Long term research plan for human factors affecting safeguards at nuclear power plants
NUREG/CR-3517:1986	Recommendations to the NRC on human engineering guidelines for nuclear power plant
NUREG/CR-4862:1987	Cognitive environment simulation – an artificial intelligence system for human performance assessment
NUREG-1384:1989	Human factors regulatory research program plan
NUREG/CR-5348:1989	Man–machine interface issues in nuclear power plants
NUREG/CR-5213:1990	The cognitive environment simulation as a tool for modeling human performance and reliability

Human Reliability Assessment (HRA)

NUREG/CR-2255:1982	Expert estimation of human error probabilities in nuclear power plant operations: review of probability assessment and scaling

NUREG/CR-1278:1983	Handbook of human reliability analysis with emphasis on nuclear power plant applications
NUREG/CR-2254:1983	A procedure for conducting a human reliability analysis for nuclear power plants
NUREG/CR-2743:1983	Procedures for using expert judgment to estimate human error probabilities in nuclear power plant operations
NUREG/CR-2744:1983	Human error data bank for nuclear power plant operations
NUREG/CR-2986:1983	The use of performance shaping factors and quantified expert judgement in the evaluation of human reliability
NUREG/CR-3010:1983	Post event human decision errors: operator action tree/time reliability correlation
NUREG/CR-3519:1985	Human error probability estimation using Licensee Event Reports
NUREG/CR-3688:1985	Generating human reliability estimates using expert judgment
NUREG/CR-3837:1985	Multiple-sequential failure model
NUREG/CR-4009:1985	Human reliability data bank
NUREG/CR-4010:1985	Specification of a human reliability data bank for conducting HRA segments of PRAs for nuclear power plants
NUREG/CR-4103:1985	Uses of human reliability analysis probabilistic risk assessment results to resolve personnel performance issues that could affect safety
NUREG/CR-4772:1987	Accident sequence evaluation program human reliability analysis procedure
NUREG/CR-4835:1989	Comparison and application of quantitative human reliability analysis methods for the risk methods integration and evaluation program (RMIEP)
NUREG/CR-5438:1990	Basic considerations in predicting error probabilities in human task performance

Hydrogen Combustion

NUREG/CR-2475:1983	Hydrogen combustion characteristics related to reactor accidents
NUREG/CR-3719:1984	Detonation calculations using a modified version of CSQ II: examples for hydrogen-air mixtures
NUREG/CR-4138:1985	Data analyses for Nevada Test Site (NTS) premixed combustion tests

Incidents

NUREG/CR-1884:1981	Observations and comments on the turbine failure at Yankee Atomic Electric Company, Rowe, Massachusetts
NUREG/CR-2993:1983	Examination of failed studs from No. 2 steam generator at the Main Yankee nuclear power station
NUREG-1154:1985	Loss of main and auxiliary feedwater event at Davis—Besse plant on June 9 1985
NUREG-1190:1986	Loss of power and water hammer event at San Onofre, Unit 1, on November 21 1985
NUREG-1195:1986	Loss of integrated control system power and overcooling transient at Rancho Seco on December 16 1985
NUREG-1410:1990	Loss of vital AC power and the residual heat removal system during mid-loop operations at Vogtle Unit 1 on March 20 1990
NUREG/CR-5622:1990	Analysis of reactor trips originating in balance of plant systems
NUREG-1455	Transformer failure and common mode loss of instrument power at Nine Mile Point Unit 2 on August 13 1991

Incident Investigation

NUREG-1303:1988	Incident investigation manual
NUREG-1303:1991	Incident investigation manual

Incident Reporting

NUREG/CR-3119:1983	Nuclear power safety reporting system
NUREG-1291:1987	BWR and PWR off-normal event descriptions

Inspection

NUREG/CR-5151:1988	Performance-based inspections
NUREG/CR-5371:1989	Development and use of risk-based inspection guides
NUREG/CR-5467:1991	Risk-based inspection guide for Crystal River Unit 3 nuclear power plant

Leak Detection

NUREG/CR-4813:1987	Assessment of leak detection systems for LWRs
NUREG/CR-5134:1988	Application of acoustic leak detection technology for the detection and location of leaks in light water reactors

Licensee Event Reports

NUREG/CR-3824:1984	CONTING program guide
NUREG-1022:1985	Licensee event report system nuclear reactor accident

NUREG/CR-3905:1985	Sequence coding and search system for Licensee Event Reports: user's guide
NUREG/CR-4071:1985	Exploratory trend and pattern analysis for 1981 Licensee Event Report data
NUREG/CR-4129:1986	Exploratory trend and pattern analysis of 1981 through 1983 Licensee Event Report data
NUREG/CR-4132:1986	Nuclear power safety reporting system final evaluation results
NUREG/CR-2000	Licensee Event Report (LER) compilation

Light Water Reactors

NUREG/CR-2278:1981	Light water reactor engineered safety features status monitoring. Final report
NUREG-1107:1984	RCSLK9 reactor coolant system leak rate determination for PWRs: user's guide
NUREG/CP-0048:1984	Proceedings of the eleventh Water Reactor Safety Research Information meeting
NUREG/CR-3593:1984	Systems interaction results from the digraph matrix analysis of a nuclear power plant's high pressure safety injection system
NUREG/CR-3943:1985	The BWR plant analyzer
NUREG/CR-4041:1985	System analysis handbook
NUREG/CR-5637:1990	Generic risk insights for Westinghouse and Combustion Engineering pressurized water reactors
NUREG/CR-5640:1990	Overview and comparison of US commercial nuclear power plants
NUREG-1430	Standard technical specifications Babcock and Wilcox plants (draft)
NUREG-1431	Standard technical specifications Westinghouse plants (draft)
NUREG-1432	Standard technical specifications Combustion Engineering plants (draft)
NUREG-1433	Standard technical specifications General Electric plants BWR (draft)

Loss of Coolant Accident (LOCA)

NUREG/CR-4393:1986	Summary of semiscale small break loss-of-coolant accident experiments (1979 to 1985)
NUREG-1230:1987	Compendium of ECCS research for realistic LOCA analysis (draft)

Loss of Fluid Test (LOFT)

NUREG/CR-3005:1985	Summary of the Nuclear Regulatory Commission's LOFT program research findings
NUREG/CR-4046:1985	Determining critical flow valve characteristics using extrapolation techniques

Loose Parts Monitoring

NUREG/CR-3008:1983	Auditory perception in loose-parts monitoring
NUREG/CR-3687:1984	Loose-part monitoring programs and recent operational experience in selected US and Western European commercial nuclear power stations

Maintenance

NUREG/CR-1369:1982	Procedures evaluation checklist for maintenance, test and calibration procedures used in nuclear power plants
NUREG/CR-1786:1982	Maintainability analysis procedure (MAP)
NUREG/CR-3541:1983	Measures of the risk impacts of testing and maintenance activities
NUREG/CR-3817:1985	Development, use and control of maintenance procedures in nuclear power plants
NUREG/CR-3883:1985	Analysis of Japanese–US nuclear power plant maintenance
NUREG/CR-4281:1985	An empirical analysis of selected nuclear power plant maintenance factors and plant safety
NUREG-1212:1986	Status of maintenance in the US nuclear power industry
NUREG/CR-4611:1986	Trends and patterns in maintenance performance in the US nuclear power industry
NUREG/CR-5666:1991	Programmatic root cause analysis of maintenance personnel performance probabilities
NUREG/CR-5695:1991	A process for risk-focused maintenance

Maintenance Personnel Reliability Model

NUREG/CR-2670:1982	Job analysis of maintenance mechanic position for the nuclear power plant maintenance personnel reliability model
NUREG/CR-2668:1983	Job analysis of the maintenance supervisor and instrument and control supervisor positions for the nuclear power plant maintenance personnel reliability model
NUREG/CR-2669:1983	Front-end analysis for nuclear power plant maintenance personnel reliability model

NUREG/CR-3274:1983	Job analysis of the instrument and control technician position for the nuclear power plant maintenance personnel reliability model
NUREG/CR-3626:1985	Maintenance personnel performance simulation (MAPPS) model: description of model content, structure and sensitivity testing
NUREG/CR-3634:1985	Maintenance personnel performance simulation (MAPPS) model: user's manual
NUREG/CR-4104:1985	Maintenance personnel performance simulation (MAPPS) model

Management and Management Systems

NUREG/CR-3601:1984	Management and organizational assessments: a review of selected organizations
NUREG/CR-3645:1984	A guide to literature relevant to the organization and administration of nuclear power plants
NUREG/CR-3737:1984	An initial empirical analysis of nuclear power plant organization and its effect on safety performance
NUREG/CR-4378:1986	Objective indicators of organizational performance at nuclear power plants
NUREG/CR-5437:1990	Organization and safety in nuclear power plants
NUREG/CR-5538:1991	Influence of organizational factors on performance reliability

Materials of Construction

NUREG/CR-3613:1985	Evaluation of welded and repair-welded stainless steel for LWR service
NUREG/CR-3911:1985	Evaluation of welded and repair-welded stainless steel for LWR service
NUREG/CR-3613:1986	Evaluation of welded and repair-welded stainless steel for LWR service

Meteorology

NUREG-0917:1982	Nuclear Regulatory Commission staff computer programs for use with meteorological data
NUREG/CR-3773:1984	Variation of planetary boundary layer dispersion properties with height in unstable conditions
NUREG/CR-3838:1984	An initial review of several meteorological models suitable for low-level waste disposal facilities
NUREG/CR-3882:1986	A method to characterize local meteorology at nuclear facilities for application to emergency response needs

Mitigation Systems

NUREG/CR-3980:1988	Survey of the start of the art in mitigation systems
NUREG/CR-5079:1989	Experimental results pertaining to thermal igniters

National Reliability Evaluation Program

NUREG/CR-2453:1982	National reliability evaluation program (NREP) options study

Non-destructive Examination

NUREG/CR-1696:1981	Integration of NDE reliability and fracture mechanics
NUREG/CR-3110:1983	Reliability of non-destructive examination
NUREG/CR-3743:1984	The impact of NDE unreliability on pressure vessel fracture predictions
NUREG/CR-4124:1985	NDE of stainless steel and on-line leak monitoring of LWRs
NUREG/CR-4368:1985	NDE of stainless steel and online leak monitoring of LWRs
NUREG/CR-4469:1986	Integration of non-destructive examination reliability and fracture mechanics
NUREG/CR-4469:1986 (sic)	Non-destructive examination (NDE) reliability for in-service inspection of light water reactors. Semi-annual report
NUREG/CR-4600:1986	Human factors study conducted in conjunction with a mini-round robin assessment of ultrasonic technician performance
NUREG-1194:1987	Construction appraisal team inspection results on welding and non-destructive examination activities
NUREG/CR-4469:1987	Non-destructive examination (NDE) reliability for in-service inspection of light water reactors
NUREG/CR-5075:1988	The SAF-UT real time inspection system: operational principles and implementation
NUREG/CR-4908:1990	Ultrasonic inspection reliability for intergranular stress corrosion cracks
NUREG/CR-5553:1990	Computer programs for eddy current defect studies

Nuclear Accidents

NUREG/CR-2591:1982	Estimating the potential impacts of a nuclear reactor accident
NUREG/CR-3566:1984	Socio-economic consequences of nuclear reactor accidents
NUREG/CR-3673:1984	Economic risks of nuclear power reactor accidents

Nuclear Accident Assessment

NUREG/CR-2326:1983	Calculations of reactor accident consequences, version 2: CRAC2 computer code
NUREG/CR-2901:1983	CRAC calculations for accident sections of environmental statements
NUREG/CR-2552:1984	CRAC2 model description
NUREG/CR-3310:1984	Testing of the CONTAIN code
NUREG/CR-4038:1985	Sensitivity and uncertainty studies of the CRAC2 computer code
NUREG/CR-4085:1985	User's manual for CONTAIN 1.0
NUREG/CR-4199:1985	A demonstration of uncertainty/ sensitivity analysis using the health and economic consequence model CRAC2
NUREG-1115:1985	Categorization of reactor safety issues from a risk perspective

Nuclear Power Plant Operation

NUREG/CR-3430:1985	Nuclear power plant operating experience
NUREG-1275:1987	Operating experience feedback report: new plants
NUREG-1272:1988	Report to the US Nuclear Regulatory Commission on analysis and evaluation of operational data
NUREG/CR-4690:1991	Generic communications index

Operating Personnel, Simulators, Training

NUREG/CP-0031:1982	Proceedings of the CSNI specialist meeting on Operator Training and Qualifications

NUREG-1220:1986	Training review criteria and procedures
NUREG/CR-4411:1986	Assessment of specialized educational programs for licensed nuclear reactor operators

NUREG/CR-4532:1986	Models of cognitive behavior in nuclear power plant personnel
NUREG/CR-4188:1986	Nuclear power plant simulation facility evaluation methodology
NUREG-1122:1987	Knowledges and abilities catalog for nuclear power plant operators
NUREG/CR-4613:1987	Evaluation of nuclear power plant operating procedures classification and interfaces
NUREG/CR-3968:1987	Study of operating procedures in nuclear power plants

Operational Safety Reliability Program

NUREG/CR-4505:1986	A scoping study of the potential effectiveness of an operational safety reliability program in addressing generic safety problems
NUREG/CR-4506:1986	An operational safety reliability program approach with recommendations for further development and evaluation

Personal Protective Equipment

NUREG/CR-2652: 1982	Evaluation and performance of closed-circuit breathing apparatus

Physics of Reactor Safety

NUREG/CR-3804:1984	Physics of reactor safety
NUREG/CR-3804:1985	Physics of reactor safety
NUREG/CR-4240:1985	Physics of reactor safety

Pipework

NUREG-0803:1981	Generic safety evaluation report regarding integrity of BWR scram system piping
NUREG/CR-2189:1981	Probability of pipe fracture
NUREG/CR-2801:1983	Piping reliability mode validation and potential use for licensing regulation development
NUREG/CR-3059:1983	Parametric calculations of fatigue crack growth in piping
NUREG/CR-3176:1983	Crack growth evaluation for small cracks in reactor coolant piping
NUREG-1061:1984	Report of the US Nuclear Regulatory Commission Piping Review Committee
NUREG/CR-3483:1984	A study of the regulatory position on postulated pipe rupture location criteria
NUREG/CR-3718:1984	Reliability analysis of stiff versus flexible piping
NUREG/CR-3869:1984	Analysis of the impact of in-service inspection using a piping reliability model
NUREG/CR-3996:1984	Response margins of the dynamic analysis of piping systems
NUREG-1061:1985	Report of the US Nuclear Regulatory Commission Piping Review Committee
NUREG/CR-1677:1985	Piping benchmark problems
NUREG/CR-3660:1985	Probability of pipe failure in the reactor coolant loops of Westinghouse PWR plants
NUREG/CR-3663:1985	Probability of pipe failure in the reactor coolant loops of Combustion Engineering PWR plants
NUREG/CR-4082:1985	Degraded piping program – Phase II
NUREG/CR-4263:1985	Reliability analysis of stiff versus flexible piping. Final project report
NUREG/CR-4291:1985	Conclusion and summary report on physical benchmarking of piping systems
NUREG/CR-4082:1986	Degraded piping program
NUREG/CR-4290:1986	Probability of pipe failure in the reactor coolant loops of Babcock and Wilcox PWR plants
NUREG/CR-4529:1986	Piping damping – experimental results from laboratory tests in the seismic range
NUREG/CR-4562:1986	Pipe damping – results of vibration tests in the 33 to 100 hertz frequency range
NUREG/CR-4574:1986	An experimental and analytical assessment of circumferential through-wall cracked pipes under pure bending
NUREG/CR-4792:1986	Probability of failure in BWR reactor coolant piping
NUREG/CR-4407:1987	Pipe break frequency estimation for nuclear power plants
NUREG/CR-4872:1987	Experimental and analytical assessment of circumferentially surface-cracked pipes under bending
NUREG/CR-4943:1987	Preparation of design specifications and design reports for pumps, valves, piping and piping supports used in safety-related portions of nuclear power plants
NUREG-1222:1988	Piping research program plan
NUREG/CR-4082:1989	Degraded piping program
NUREG/CR-4792:1989	Probability of failure in BWR reactor coolant piping
NUREG/CR-5287:1989	Closeout of NRC Bulletin 87–01: thinning of pipe walls in nuclear power plants
NUREG/CR-5603:1990	Pressure-dependent fragilities for piping components

NUREG/CR-5757:1991	Verification of piping response calculation of SMACS code with data from seismic testing of an in-plant piping system

Pipe Whip

NUREG/CR-1721:1981	Computer code development for pipe whip and impact analysis
NUREG/CR-3686:1984	WIPS – computer code for whip and impact analysis of piping systems
NUREG/CR-3231:1987	Pipe-to-pipe impact program
NUREG/CR-5014:1987	Parametric study of pipe whip analysis

Plant Operation

NUREG/CR-2378: 1982	Nuclear power plant operating experience 1980

Population Distribution

NUREG/CR-3056:1984	Population distribution analysis for nuclear power plant siting

Power Supply

NUREG/CR-2989:1983	Reliability of emergency AC power system at nuclear power plants
NUREG/CR-3226:1983	Station blackout accident analyses
NUREG-1032:1985	Evaluation of station blackout accidents at nuclear power plants (draft)
NUREG-1109:1986	Regulatory analysis for the resolution of unresolved safety issue A-44, station blackout
NUREG/CR-4466:1986	Station blackout transients in the semiscale facility
NUREG/CR-4470:1986	Survey and evaluation of vital instrumentation and control power supply events
NUREG/CR-4533:1986	Program to analyze the failure mode of lead-acid batteries
NUREG/CR-4564:1986	Operating experience and aging–seismic assessment of battery chargers and inverters
NUREG/CR-4942:1987	Equipment operability during station blackout events
NUREG-1032:1988	Evaluation of station blackout accidents at nuclear power plants
NUREG-1109:1988	Regulatory/backflt analysis for the resolution of unresolved safety issue A-44: station blackout
NUREG/CR-5032:1988	Modeling time to recovery and initiating event frequency for loss of offsite power incidents at nuclear power plants

Precursors to Potential Accidents

NUREG/CR-2497: 1982	Precursors to potential severe core damage accidents: 1969–1979
NUREG/CR-3591:1984	Precursors to potential severe core damage accidents
NUREG/CR-4674:1991	Precursors to potential severe core damage accidents 1990: a status report

Pressure Systems

NUREG/CR-3604:1984	Bolting applications
NUREG/CR-3853:1984	Preloading of bolted connections in nuclear reactor component supports
NUREG/CR-3228:1985	Structural integrity of water reactor pressure boundary components

Pressure Vessels

NUREG/CR-2308:1982	Design criteria for the spacing of nozzles and reinforced openings in cylindrical nuclear pressure vessels and pipe
NUREG/CR-4267:1985	Vessel integrity (VISA) simulation code sensitivity study
NUREG/CR-4486:1986	VISA II: a computer code for predicting the probability of reactor pressure vessel failure
NUREG/CR-4614:1986	VISA II sensitivity study of code calculations input and analytical model parameters

Probabilistic Risk Assessment

NUREG/CR-2300:1981	PRA procedures guide (draft)
NUREG/CR-2300:1982	PRA procedures guide (draft)
NUREG/CR-2300:1983	PRA procedures guide
NUREG-1050:1984	Probabilistic risk assessment (PRA) reference document
NUREG/CR-2815:1984	Probabilistic safety analysis procedure
NUREG-1093:1984	Reliability and risk analysis methods research plan
NUREG/CR-3440:1984	Identification of severe accident uncertainties
NUREG/CR-3852:1984	Insight into PRA methodologies
NUREG/CR-2815:1985	Probabilistic safety analysis procedures guide
NUREG/CR-3485:1985	PRA review manual
NUREG/CR-3887:1985	Human factors review for severe accident sequence analysis
NUREG/CR-3904:1985	A comparison of uncertainty and sensitivity analysis techniques for computer models
NUREG/CR-4229:1985	Evaluation of current methodology employed in probabilistic risk assessment (PRA) of fire events at nuclear power plants
NUREG/CR-4231:1985	Evaluation of available data for probabilistic risk assessment (PRA) of fire events at nuclear power plants
NUREG/CR-4350:1985	Probabilistic risk assessment course documentation

NUREG/CR-4377:1985	Evaluations and utilizations of risk importances
NUREG/CR-3969:1986	Independent code assessment: Sandia-proposed accuracy quantification methodology
NUREG/CR-4372:1986	Probabilistic risk assessment (PRA) applications
NUREG/CR-4514:1986	Controlling principles for prior probability assignments in nuclear risk assessment
NUREG/CR-4405:1987	Probabilistic risk assessment (PRA) insights
NUREG/CR-4836:1988	Approaches to uncertainty analysis in probabilistic risk assessment
NUREG/CR-5050:1988	Annotated bibliography of reliability and risk data sources
NUREG/CR-5323:1989	Validation of risk-based performance indicators: safety system function trends
NUREG/CR-5425:1989	Evaluation of allowed outage times (AOTs) from a risk and reliability standpoint
NUREG/CR-5262:1990	PRAMIS: probability risk assessment model integration system
NUREG/CR-5477:1990	An evaluation of the reliability and usefulness of external initiator PRA methodologies
NUREG/CR-5520:1991	Procedures guide for extracting and loading probabilistic risk assessment data into MAR-D using IRRAS 2.5

Pumps

NUREG/CR-1205:1982	Data summaries of Licensee Event Reports of pumps at US commercial nuclear power plants
NUREG/CR-2886:1983	The in-plant reliability data base for nuclear power components: interim data report – the pump component
NUREG/CR-3650:1984	A statistical analysis of nuclear power plant pump failure rate variability
NUREG/CR-3914:1985	Pump and valve qualification review guide
NUREG/CR-4077:1985	Reactor coolant pump shaft seal behavior during station blackout
NUREG/CR-4400:1985	The impact of mechanical- and maintenance-induced failures of main reactor coolant pump seals on plant safety
NUREG/CR-4544:1986	Reactor coolant pump seal related instrumentation and operator response
NUREG/CR-4821:1987	Reactor coolant pump shaft seal stability during station blackout
NUREG/CR-4948:1989	Technical findings related to generic issue 23: reactor coolant pump seal failure
NUREG/CR-5706:1991	Potential safety-related pump loss. An assessment of industry data

Quality Assurance

NUREG-1055:1984	Improving quality and the assurance of quality in the design and construction of commercial nuclear power plants
NUREG/CR-4678:1986	A method for using PRA to establish quality program applicability
NUREG/CR-4921:1987	Engineering and quality assurance cost factors associated with nuclear plant modification

Reactor Safety Research

NUREG/CR-2127:1982	Reactor safety research programs: quarterly report
NUREG/CR-2716:1982	Reactor safety research programs: quarterly report
NUREG/CR-2531:1983	Introductory user's manual for the US Nuclear Regulatory Commission reactor safety research data bank
NUREG/CR-3307:1984	Reactor safety research programs
NUREG/CR-3810:1984	Reactor safety research programs
NUREG-1080:1985	Long-range research plan
NUREG-1155:1985	Research program plan
NUREG/CP-0058:1985	Proceedings of the twelfth Water Reactor Safety Research Information meeting
NUREG/CR-3810:1985	Reactor safety research programs
NUREG/CR-3816:1985	Reactor safety research
NUREG/CR-4318:1985	Reactor safety research programs
NUREG/CR-4340:1985	Reactor safety research semi-annual report
NUREG/CR-4340:1986	Reactor safety research semi-annual report
NUREG/CR-4805:1987	Reactor safety research seminar annual report
NUREG-1260:1988	A report to Congress on nuclear regulatory research
NUREG/CR-5039:1988	Reactor safety research semiannual report
NUREG/CR-2331:1990	Safety research programs sponsored by the Office of Nuclear Regulatory Research

Reactor Safety Study

NUREG/CR-1659:1981	Reactor Safety Study methodology applications program
NUREG/CR-1879:1981	Sensitivity of risk parameters to human errors in Reactor Safety Study for a PWR

NUREG/CR-2906:1983	Sensitivity of risk parameters component unavailability in Reactor Safety Study (PSAP/PSAB computer codes)
NUREG/CR-2531:1985	Introductory user's manual for the US Nuclear Regulatory Commission Reactor Safety Research Data Bank

Regulation

NUREG-0834:1981	NRC licensee assessments
NUREG/CP-0017:1981	Executive seminar on the Future Role of Risk Assessment and Reliability Engineering in Nuclear Regulation
NUREG/CR-1750:1981	Analysis, conclusions and recommendations concerning operator licensing
NUREG/CR-2040:1981	A study of the implications of applying quantitative risk criteria in the licensing of nuclear power plants in the United States
NUREG-0845:1982	Agency procedures for the NRC incident response plan
NUREG/CR-2664:1982	Selected review of foreign licensing practices for nuclear power plants

NUREG/CR-2015:1981	Seismic safety margins research program. Phase I Final Report – overview
NUREG/CR-1120:1982	Seismic safety margins research program
NUREG/CR-2405:1982	Subsystem fragility: seismic safety margins research program
NUREG-0967:1983	Seismic hazard review for the systematic evaluation program – a use of probability in decision-making
NUREG/CR-1582:1983	Seismic hazard analysis – overview and executive summary
NUREG/CR-2015:1983	Seismic safety margins research program
NUREG/CR-2945:1983	Characterization of earthquake forces for probability-based design of nuclear structures
NUREG/CR-3315:1983	A consensus estimation study of nuclear power plant structural loads (seismic)
NUREG/CR-3342:1983	Probabilistic models for operational and accidental loads on seismic category I structures
NUREG/CR-3357:1983	Identification of seismically risk sensitive systems and components in nuclear power plants
NUREG/CR-3127:1984	Probabilistic seismic resistance of steel containments

NUREG/CR-3480:1984	Value/impact assessment for seismic design criteria USI A-40
NUREG/CR-3756:1984	Seismic hazard characterization of the eastern United States
NUREG/CR-3811:1984	Alternate procedures for the seismic analysis of multiply supported piping systems
NUREG-1147:1985	Seismic safety research program plan
NUREG/CP-0059:1985	Proceedings of the MITI-NRC Seismic Information Exchange meeting
NUREG/CR-3805:1985	Engineering characterization of ground motion
NUREG/CR-4145:1985	Earthquake recurrence intervals at nuclear power plants: analysis and ranking
NUREG/CR-4331:1985	Simplified seismic probabilistic risk assessment
NUREG/CR-4334:1985	An approach to the quantification of seismic margins in nuclear power plants
NUREG/CR-4430:1985	Current methodologies for assessing the potential for earthquake-induced liquefaction in soils
NUREG/CR-3805:1986	Engineering characterization of ground motion
NUREG/CR-4431:1986	Summary report on the seismic safety margins research program
NUREG/CR-4482:1986	Recommendations to the Nuclear Regulatory Commission on trial guidelines for seismic margin reviews of nuclear power plants (draft)
NUREG/CR-4822:1987	Broad band seismic data analysis
NUREG/CR-4903:1987	Selection of earthquake resistant design criteria for nuclear power plants
NUREG/CR-5073:1988	Quantification of margins in piping system seismic response
NUREG/CR-5076:1988	An approach to the quantification of seismic margins in nuclear power plant
NUREG/CR-3006:1989	Damping in building structures during earthquakes
NUREG/CR-5098:1989	An analytical study of seismic threat to containment integrity
NUREG/CR-5250:1989	Seismic hazard characterization of 69 nuclear power plants east of the Rocky Mountains
NUREG/CR-5270:1989	Assessment of seismic margin calculation methods

Seismic Fragility

NUREG/CP-0070:1985	Proceedings of the workshop on Seismic and Dynamic Fragility of Nuclear Power Plant Components
NUREG/CR-3558:1985	Handbook of nuclear power plant seismic fragilities
NUREG/CR-4123:1985	Seismic fragility of reinforced concrete structures and components for application to nuclear facilities
NUREG/CR-4659:1986	Seismic fragility of nuclear power plant components (Phase 1)
NUREG/CR-4734:1987	Seismic testing of typical containment piping penetration systems
NUREG/CR-4776:1987	Response of seismic category I tanks to earthquake excitation
NUREG/CR-4859:1987	Seismic fragility test of a 6-inch diameter pipe system
NUREG/CR-4899:1987	Component fragility research program
NUREG/CR-4910:1987	Relay chatter and operator response after a large earthquake
NUREG/CR-5588:1990	CARES (computer analysis for rapid evaluation of structures). Version 1
NUREG/CR-4659:1991	Seismic fragility of nuclear power plant components (Phase II). A fragility handbook of eighteen components.

Seismic and Dynamic Qualification

NUREG-1018:1983	Seismic qualification of equipment in operating plants
NUREG/CR-1161	Recommended revisions to Nuclear Regulatory Commissions seismic design criteria
NUREG/CR-3266:1983	Seismic and dynamic qualification of safety-related electrical and mechanical equipment in operating nuclear power plants
NUREG/CR-3630:1984	Equipment qualification methodology research: tests of pressure switches
NUREG/CR-3875:1984	The use of in-situ procedures for seismic qualification of equipment in currently operating plants
NUREG-1030:1985	Seismic qualification of equipment in operating nuclear power plants (draft)
NUREG-1209:1986	Program plan for environmental qualification of mechanical and dynamic (including seismic) qualification of mechanical and electrical equipment program (EDQP)
NUREG/CR-3137:1986	Seismic and dynamic qualification of related electrical and mechanical equipment

NUREG-1030:1987	Seismic qualification of equipment in operating nuclear power plants
NUREG-1211:1987	Regulatory analysis for resolution of unresolved safety issue A-46: seismic qualification of equipment in operating plants

Severe Accident Risk Reduction Program

NUREG-0900:1986	Nuclear power plant severe accident research plan
NUREG/CR-4569:1986	A review of the severe accident risk reduction program (SARRP) containment event trees
NUREG/CR-4781:1987	Study of severe accident mitigation systems
NUREG/CR-5132:1988	Severe accidents insight report
NUREG/CR-4551:1990	Evaluation of severe accident risks: quantification of major input parameters
NUREG/CR-4551:1991	Evaluation of severe accident risks: quantification of major input parameters
NUREG/CR-5809:1991	An integrated structure and scaling methodology for severe accident technical issue resolution (draft)

Severe Accident Risk Report (NUREG-1150)

NUREG-1150:1987	Reactor risk reference document (draft)
NUREG/CR-5000:1988	Methodology for uncertainty estimation in NUREG-1150 (draft)
NUREG/CR-5113:1988	Findings of the peer review panel on the draft reactor risk reference document NUREG 1150
NUREG-1420:1990	Special committee review of the Nuclear Regulatory Commission's severe accident risk report (NUREG-1150)
NUREG-1150:1990	Severe accident risks: an assessment for five US nuclear power plants
NUREG/CR-4840:1990	Procedures for the external event core damage frequency analyses for NUREG-1150
NUREG-1150:1991	Severe accident risks: an assessment for five US nuclear power plants

Sizewell B

NUREG-0999:1983	Sizewell B – analysis of British application of US PWR technology

Siting

NUREG/CR-1684: 1981	A comparison of site evaluation methods

SLIM-MAUD

NUREG/CR-3518:1984	SLIM-MAUD: an approach to assessing human error probabilities using structured expert judgment
NUREG/CR-4016:1987	Application of SLIM-MAUD: a test of an interactive computer-based method for organizing expert assessment of human performance and reliability

Source Terms

NUREG-0856:1985	Reassessment of the technical bases for estimating source terms (draft)
NUREG-0956:1985	Reassessment of the technical bases for estimating source terms (draft)
NUREG-0956:1986	Reassessment of the technical bases for estimating source terms
NUREG/CR-4587:1986	Source term code package: a user's guide (MOD1)
NUREG/CR-4656:1986	Verification tests calculations for the source term code package
NUREG/CR-4688:1986	Quantification and uncertainty analysis of source terms for severe accidents in light water reactors (QUASAR)
NUREG-1265:1987	Uncertainty papers on severe accident source terms
NUREG/CR-4722:1987	Source term estimation using MENU-TACT
NUREG/CR-4883:1987	Review of research on uncertainties in estimates of source terms from severe accidents in nuclear power plants
NUREG-1228:1988	Source term estimation during incident response to severe nuclear power plant accidents
NUREG/CR-5531:1991	MELCOR 1.8: a computer code for nuclear reactor severe accident source term and risk assessment analyses

Steam Generators

NUREG/CR-4079:1985	Analytic studies pertaining to steam generator tube rupture accidents
NUREG/CR-4276:1985	Vibration and wear in steam generating tubes following chemical clearning
NUREG/CR-4276:1986	Vibration and wear in steam generating tubes following chemical clearning

Steam Supply

NUREG-0852:1987	Safety evaluation report related to the final design of the standard nuclear steam supply reference system CESSAR

NUREG-1413	Safety evaluation report related to the preliminary design of the standard steam supply reference system RESAR

Structures

NUREG/CR-2347:1982	Margins to failure – category I structures program: background and experimental program plan
NUREG/CR-2638:1982	Snow loads for the design of nuclear power plant structures
NUREG/CR-3628:1984	Probability based safety checking of nuclear plant structures

System Interactions

NUREG/CR-3922:1985	Survey and evaluation of system interaction events and sources
NUREG/CR-4261:1986	Assessment of system interaction experience in nuclear power plants

Thermal Hydraulic Analysis

NUREG/CR-1157:1981	Thermal/hydraulic analysis research program: quarterly report
NUREG/CR-1998:1981	RELAP4/MOD7: a best estimate computer program to calculate thermal and hydraulic phenomena in a nuclear reactor or related system
NUREG/CR-1826:1982	RELAP5/MOD1 code manual
NUREG/CR-3046:1983	COBRA/TRAC – a thermal hydraulics code for transient analysis of nuclear reactor vessels and primary coolant
NUREG/CR-3257:1983	RELAP5 assessment: LOFT turbine trip L6–7/L9–2
NUREG/CR-2896:1984	COMMIX 1A a three-dimensional transient single-phase computer program for thermal hydraulic analysis of single and multicomponent systems
NUREG/CR-3329:1984	Thermal/hydraulic analysis research program
NUREG/CR-3504:1984	Turbulence modeling in the COMMIX computer code
NUREG/CR-3772:1985	RELAP5 assessment: semiscale small break tests S-UT-1, S-UT-2, S-UT-6, S-UT-7 and S-UT-8
NUREG/CR-3802:1985	RELAP5 assessment: quantitative key parameters and run time statistics
NUREG/CR-3820:1985	Thermal/hydraulic analysis research program (TRAC-PF1/MOD1)
NUREG/CR-3936:1985	RELAP5 assessment: conclusions and user guidelines
NUREG/CR-4278:1985	TRAC-PF1/MOD1 development assessment
NUREG/CR-4292:1985	A comparative analysis of constitutive relations in TRAC-PFL and RELAP5/MOD1
NUREG/CR-3262:1986	COBRA-NC: a thermal hydraulic code for transient analysis of nuclear reactor components
NUREG/CR-4371:1986	COMMIX-2: a three-dimensional transient computer program for thermal – hydraulic analysis of two-phase flows
NUREG/CR-4830:1987	MELCOR validation and verification 1986 papers
NUREG/CR-4312:1988	RELAP5/MOD2 code manual
NUREG/CR-5194:1988	RELAP5/MOD2 models and correlations
NUREG/CR-5273:1989	SCDAP/RELAP5/MOD2 code manual

Three Mile Island

NUREG-0680:1981	TMI-1 restart
NUREG-0752:1981	Control room design report for TMI-1
NUREG-0698:1984	NRC plan for cleanup operations at Three Mile Island Unit 2
NUREG/CR-4978:1987	The cooldown aspects of the TMI-2 accident
NUREG-1355:1989	The status of recommendations of the President's Commission on the Accident at Three Mile Island. A ten-year review
NUREG/CR-5457:1989	A review of the Three Mile Island-1 probabilistic risk assessment

Toxic Gas

NUREG/CR-1741:1981	Models for the estimation of incapacitation times following exposure to toxic gases or vapors
NUREG/CR-3685:1984	Toxic gas accident analysis code user's manual
NUREG/CR-5656:1991	EXTRAN: a computer code for estimating concentrations oftoxic substances at control room air intakes
NUREG/CR-5669:1991	Evaluation of exposure limits to toxic gases for nuclear reactor control room operators

Transport

NUREG/CR-3499:1983	Severe rail and truck accidents:toward a definition of bounding environments for transportation packages
NUREG/CR-5717:1991	Packaging supplier inspection guide

Two-Phase Flow

NUREG/CR-2671:1982	The Marviken full scale critical flow tests
NUREG/CR-3372:1983	An analysis of wave dispersion, sonic velocity and critical flow in two-phase mixtures
NUREG/CR-4761:1986	Small break critical discharge – roles of vapor and liquid entrainment in stratified two-phase region upstream of the break

Utilities

NUREG/CR-2796:1982	Compressed air and backup nitrogen systems in nuclear power plants
NUREG/CR-2797:1982	Evaluation of events involving service water systems in nuclear power plants
NUREG/CR-3351:1985	Safety implications associated with in-plant pressurized gas storage
NUREG/CR-5472:1990	A risk-based review of instrument air systems at nuclear power plants distribution

Value-Impact Analysis

NUREG/CR-4941:1987	The application of value-impact analysis to USI A-45
NUREG/CR-5579:1990	Value/impact assessment of jet impingement loads and pipe-to-pipe impact damage

Valves

NUREG/CR-1363:1982	Data summaries of Licensee Event Reports of valves at US commercial nuclear power plants
NUREG/CR-3154:1983	The in-plant reliability data base for nuclear power components: interim data report – the valve component
NUREG/CR-3914:1985	Pump and valve qualification review guide
NUREG/CR-4141:1985	Containment purge and vent valve test program. Final report
NUREG/CR-4648:1986	A study of typical nuclear containment purge valves in an accident environment
NUREG/CR-4692:1987	Operating experience review of failures of power operated relief valves and block valves in nuclear power plants
NUREG/CR-4999:1988	Estimation of risk reduction from improved PORV reliability in PWRs
NUREG/CR-5159:1988	Prediction of check valve performance and degradation in nuclear power plant systems
NUREG-1316:1989	Technical findings and regulatory analysis related to generic issue 70. Evaluation of power operated relief valve and block valve reliability in PWR nuclear power plants
NUREG-1352:1990	Action plans for motor-operated valves and check valves
NUREG-1372:1990	Regulatory analysis for the resolution of generic issue C-8 'Main steam isolation valve leakage and LCS failure'
NUREG/CR-5583:1990	Prediction of check valve performance and degradation in nuclear power plant systems – wear and impact

Water Hammer

NUREG-0918:1982	Prevention and mitigation of steam generator water hammer events in PWR plants
NUREG/CR-2059:1982	Compilation of data concerning known and suspected water hammer events in nuclear powerplants
NUREG/CR-2781:1982	Evaluation of water hammer events in light water reactors
NUREG-0927:1983	Evaluation of water hammer experience in nuclear power plants
NUREG-0927:1984	Evaluation of water hammer occurrence in nuclear power plants
NUREG-0993:1984	Regulatory analysis for USI A-1: 'water hammer'
NUREG/CR-3939:1984	Water hammer, flow induced vibration and safety/relief valve loads
NUREG/CR-5220:1988	Diagnosis of condensation-induced water hammer

Particular Nuclear Power Stations

A Technical specifications for (name) station

B Safety evaluation report related to the operation of (name) station

	A – Technical specification	B–Safety evaluation
Beaver Valley	1259, 1279	1057
Braidwood	1223, 1261, 1276	1002
Byron	1097, 1113	0876
Calaway		0830
Catawba	1072, 1099, 1106, 1182, 1191	0954
Clinton	1202, 1235	0853
Comanche Peak		0797
Diablo Canyon	0817, 1132, 1151	0675
Enrico Fermi	1089, 1141	0798
Grand Gulf		0831
Hope Creek	1186, 1202	1048
LaSalle	1013	0519
Limerick	1088, 1149	0974, 0991
Millstone	1161, 1176	1031
Nine Mile Point	1193, 1253	1047

Onofre		0712
Palisades	1424	
Palo Verde	1111, 1133, 1173 1181, 1248, 1287	0857
Perry	1162, 1204	0887
River Bend	1142, 1172	0989
Salem		0517
San Onofre	1443	
Seabrook	1207, 1331	0896
Shearon Harris	1208, 1240	1038
Shoreham	1012, 1126	0420
South Texas Project	1255, 1334	0781
Susquehanna	1042	0776
Vogtle	1237, 1247, 1343	1137
Waterford	1117	0787
Watts Bar		0847
Wolf Creek	1104, 1136	0881

Appendix 29

Information Sources

Contents

A29.1 Selected Organizations Relevant to Safety and Loss Prevention

United Kingdom

Associated Octel Company Limited,
http://www.octel-corp.com/home/home.htm
P.O. Box 17, Oil Sites Road, Ellesmere Port,
Cheshire, CH65 4HF
Phone: +44 (0) 151 355 3611, Fax: +44 (0) 151 356 2349

Association of British Chemical Manufacturers – succeeded by Chemical Industries Association
Association of British Insurers,
http://www.abi.org.uk/
51 Gresham Street, London EC2V 7HQ
Phone: +44 (0) 20 7600 3333, Fax: +44 (0) 20 7696 8999

British Approvals Service for Electrical Equipment in Flammable Atmospheres (BASEEFA) – succeeded by Electrical Equipment Certification Service

British Chemical Engineering Contractors Association (BCECA),
http://www.bceca.org.uk/
1 Regent Street, London SW1Y 4NR
Phone: +44 (0) 20 7839 6514

British Chemical Industries Safety Council – succeeded by Chemical Industries Association

British Cryogenic Council (BCC) – succeeded by British Cryoengineering Society (BCS)

British Cryoengineering Society (BCS),
http://www.bcryo.org.uk/
P.O. Box 41, Leatherhead, KT22 9YY
Phone: +44 (0) 1372 376544, Fax: +44 (0) 1372 376544

British Compressed Gas Association (BCGA),
http://www.bcga.co.uk/
6 St Mary's St, Wallingford, OX10 0EL
Phone: +44 (0) 1491 825533, Fax: +44 (0) 1491 826689

British Computer Society (BCS),
http://www1.bcs.org.uk/
1 Sanford Street, Swindon, Wiltshire, SN1 1HJ
Phone: +44 (0) 1793 417417, Fax: +44 (0) 1793 480270

British Engine Insurance Company,
39 Windsor Place, Cardiff South Glamorgan, CF10 3BW
Phone: +44 (0) 29 20237199

British Fire Services Association,
http://www.bfsa.org.uk/
86 London Road, Leicester LE2 OQR
Phone: +44 (0) 116 2542879, Fax: +44 (0) 116 2542879

British Geological Survey,
Murchison House, West Mains Road, Edinburgh EH9 3LA
Phone: +44 (0) 131 667 1000, Fax: +44 (0) 131 668 2683

British Hydromechanics Research Association – succeeded by BHR Group Limited

BHR GROUP Limited
http://www.bhrgroup.co.uk/
The Fluid Engineering Centre, Cranfield,
Bedfordshire MK43 OAJ
Phone: +44 (0) 1234 750422, Fax: +44 (0) 1234 750074

British Insurance Association – succeeded by Association of British Insurers

British Nuclear Society (BNES),
http://www.bnes.com/
1-7 Great George Street, London, SW1P 3AA
Phone: +44 (0) 20 7665 2241, Fax: +44 (0) 20 7799 1325

British Occupational Hygiene Society (BoHS),
http://www.bohs.org/
Suite 2, Georgian House, Great Northern Road,
Derby, DE1 1LT
Phone: +44 (0) 1332 298101, Fax: +44 (0) 1332 298099

British Pump Manufacturers Association (BPMA),
http://www.bpma.org.uk/
The McLaren Building, 35 Dale End, Birmingham, B4 7LM
Phone: +44 (0) 121 200 1299, Fax: +44 (0) 121 200 1306

British Rail – privatized and succeeded by the Rail Industry Training Council (RITC Ltd)

British Red Cross Society,
http://www.redcross.org.uk/
9 Grosvenor Crescent, London SW1X 7EJ
Phone: +44 (0) 20 7235 5454, Fax: +44 (0) 20 7245 6315

British Safety Council,
http://ww2.britishsafetycouncil.org/
70 Chancellors Road, London W6 9RS
Phone: +44 (0) 20 8741 1231, Fax: +44 (0) 20 8741 4555

British Standards Institution (BSI),
http://www.bsi-global.com/
389 Chiswick High Road, London, W4 4AL
Phone: +44 (0) 20 8996 9000, Fax: +44 (0) 20 8996 7001

British Waterways,
http://www.britishwaterways.co.uk/
Willow Grange, Church Road, Watford, WD17 4QA
Phone: +44 (0) 1923 201 120

Building Research Establishment Ltd (BRE),
http://www.bre.co.uk/
Garston, Watford WD25 9XX
Phone: +44 (0) 1923 664 000

Chamber of Shipping of the UK,
http://www.british-shipping.org/
Carthusian Court, 12 Carthusian Street,
London EC1M 6EZ
Phone: +44 (0) 20 7417 2800, Fax: +44 (0) 20 7726 2080

Chemical and Allied Product Industry Training Board – now disbanded

Chemical Industries Association (CIA),
http://www.cia.org.uk/
Kings Buildings, Smith Square, London SW1P 3JJ
Phone: +44 (0) 20 7834 3399, Fax: 020 7834 4469

Chemical Industry Safety and Health Council – succeeded by Chemical Industries Association

The Chemical Society – see the Royal Society for Chemistry

Chief and Assistant Fire Officers Association (CACFOA),
http://www.fire-uk.org/
9-11 Pebble Close, Tamworth, Staffordshire, B77 4RD
Phone: +44 (0) 1827 302300, Fax: +44 (0) 1827 302399

Confederation of British Industry (CBI),
http://www.cbi.org.uk/
103 New Oxford Street, London WC1A 1DU
Phone: +44 (0) 20 7379 7400, Fax: +44 (0) 20 7240 8287

Council for Oil and Gas Extraction, Chemicals Manufacturing and Petroleum Industries (COGENT)
http://www.cogent-ssc.com/
Monticello House, 45 Russell Square, London WC1B 4JP
Phone: +44 (0) 20 637 9533, Fax: +44 (0) 20 7291 6129

Electrical Equipment Certification Service (EECS) – part of HSE but disbanded in 2002

Engineering Council, (UK),
http://www.engc.org.uk/
10 Maltravers Street, London WC2R 3ER
Phone: +44 (0) 20 7240 7891, Fax: +44 (0) 20 7379 5586

Engineering Equipment Users Association – succeeded by Engineering Equipment and Materials Users Association

Engineering Equipment and Materials Users Association,
http://www.eemua.co.uk/
3rd Floor, 30 Long Lane, London EC1A 9HL
Phone: +44 (0) 20 7796 1293, Fax: +44 (0) 20 7796 1294

The Fellowship of Engineering – now The Royal Academy of Engineering

Fire Officers Committee – see Association of British Insurers

Fire Protection Association (FPA),
http://www.thefpa.co.uk/
Bastille Court, 2 Paris Garden, London SE1 8ND
Phone: +44 (0) 20 7902 5300, Fax: +44 (0) 20 7902 5301

Fire Industry Confederation (FIC)
http://www.the-fic.org.uk/
Neville House, 55 Eden Street, Kingston upon Thames, Surrey, KT1 1BW
Phone: +44 (0) 20 8549 8839, Fax: +44 (0) 20 8547 1564

Fire Research Station (FRS),
http://www.bre.co.uk/frs/
FRS, the Fire Division of BRE, Garston, Watford WD25 9XX
Phone: +44 (0) 1923 664700, Fax: +44 (0) 1923 664910

Fire Service College,
http://www.fireservicecollege.ac.uk/
Friends of the Earth Ltd.,
http://www.foe.co.uk/
26-28 Underwood Street, London N1 7JQ
Phone: +44 (0) 20 7490 1555, Fax: +44 (0) 20 7490 0881

Health and Safety Commission/Executive (HSC/E),
http://www.hse.gov.uk/
2 Rose Court, 2 Southwark Bridge, London SE1 9HS
Phone: +44 (0) 20 7556 2100, Fax: +44 (0) 20 7556 2109

Health and Safety Executive,
Research and Laboratory Division,
http://www.hse.gov.uk/research/
Broad Lane, Sheffield, S3 7HQ
Phone: +44 (0) 114 289 2000, Fax: +44 (0) 114 289 2500

High Pressure Technology Association,
http://www.liv.ac.uk/~js1/hpta.html
c/o Department of Chemistry, University of Liverpool, Liverpool L69 7ZD
Phone: +44 (0) 151 794 3530, Fax: +44 (0) 151 794 3588

HM Stationery Office (HMSO),

Appendix

30

Units and Unit Conversions

Contents

SI units are used in this book unless otherwise stated, these are described in BS 5555:1981 *SI Units and Recommendations for the Use of their Multiples and of Certain Other Units*.

Table A30.1 gives selected references on units.

A30.1 Absolute and Gauge Pressures

It is common practice to attach to units of pressure an 'a' or a 'g', denoting 'absolute' or 'gauge', respectively (e.g. bara, psig). This is not part of the SI system, where instead the designation 'absolute' or 'gauge' or some other defining term is applied to the pressure described. In this book both practices are used.

A30.2 Other Units and Conversions

Some other units which are used in the book are

Table A30.1 *Selected references on units*

Chappelear (1981); Horvath (1986); Mullin (1986)

A30.2.1 Volumetric flux

1 l/m^2 s = 10^{-3} m^3/m^2 s
1 l/m^2 min = 1.667×10^{-5} m^3/m^2 s
1 UK gal/ft^2 min = 8.149×10^{-4} m^3/m^2 s
1 US gal/ft^2 min = 6.791×10^{-4} m^3/m^2 s

A30.2.2 Other quantities

SI unit conversion

Conversions of other units to and from SI units are given in tables compiled by Mullin (1967) and Lees (1968). The conversion table given by the latter is reproduced in Table A30.2.

1 bbl (barrel) = 42 US gal
1 lusec = 10^{-3} torr l/s
1 micron = 10^{-6} m
1 mil = 10^{-3} in. = 2.540×10^{-5} m
1 torr = 1 mmHg = 1.333×10^{2} N/m^2

Table A30.2 *SI unit conversion tables (Lees, 1968)*

Acceleration	1 cm/s^2	1.0000×10^{-2} m/s^2
	1 m/h^2	7.7160×10^{-8} m/s^2
	1 ft/s^2	3.0480×10^{-1} m/s^2
	1 ft/h^2	2.3519×10^{-8} m/s^2
	1 g	9.8067 m/s^2
Area	1 cm^2	1.0000×10^{-4} m^2
	1 ft^2	9.2903×10^{-2} m^2
	1 in.^{2}	6.4516×10^{-4} m^2
	1 yd^2	8.3613×10^{-1} m^2
	1 acre	4.0469×10^{3} m^2
	1 mile^2	2.5900×10^{6} m^2
	1 ha	1.0000×10^{4} m^2
Calorific value (volumetric)	1 cal/cm^3	4.1868×10^{6} J/m^3
	1 kcal/m^3	4.1868×10^{3} J/m^3
	1 Btu/ft^3	3.7260×10^{4} J/m^3
	1 Chu/ft^3	6.7067×10^{4} J/m^3
	1 therm/ft^3	3.7260×10^{9} J/m^3
	1 kcal/ft^3	1.4786×10^{5} J/m^3
Coefficient of expansion (volumetric)	1 g/cm^3 °C	1.0000×10^{3} kg/m^3 °C
	1 lb/ft^3 °F	2.8833×10 kg/m^3 °C
	1 lb/ft^3 °C	1.6018×10 kg/m^3 °C
Density	1 g/cm^3	1.0000×10^{3} kg/m^3
	1 lb/ft^3	1.6018×10 kg/m^3

Process Safety Management (PSM) Regulation in the United States

Contents

The history of safety regulations in the United States can be traced back to the year before the beginning of the twentieth century. The River and Harbor Act, the first known federal legislation in the United States relevant to safety was promulgated in 1899. This Act prohibited the creation of any obstruction not authorized by the US Congress, to the navigable capacity of any waters of the United States except on plans authorized by the Secretary of the Army. The Act was promulgated expressly to protect the nation's waterways from excessive dumping. Subsequent to the River and Harbor Act, the US Congress has passed numerous laws, which impose environmental or safety regulations on businesses. Since then, the total number of legislations has steadily increased. In addition to the federal government, local entities such as the state, county, and cities have also promulgated regulations and ordnances, which impose safety requirements on process facilities.

In 1936, the United States federal government enacted the Walsh–Healy Act to establish federal safety and health standards for activities relating to federal contracts. The Walsh–Healy Act led to early research into the identification and control of occupational diseases. The ideas behind this Act are the basis of many of today's occupational health and safety regulations.

In 1970, Congress promulgated the Occupational Safety and Health Act (OSHA). As a result of this landmark legislation, OSHA and the National Institute for Occupational Safety and Health (NIOSH) were established within the Department of Labor and the Department of Health and Human Services respectively. OSHA's mission is to, 'Assure so far as possible every working man and woman in the nation safe and healthful working conditions'. The OSHAct allows OSHA to set and enforce standards that require employers to maintain safe and healthful workplaces. NIOSH, on the other hand, does not have any regulatory or enforcement authority, but is charged with the responsibility of training of professionals and with the research and recommendation of new regulations to the Secretary of Labor.

In 1990, EPA analysed chemical incidents in the early to mid-1980s and compared them to the Bhopal incident. The analysis concluded that 17 incidents released sufficient volumes of chemicals that could have been more severe than Bhopal if the weather conditions and plant location were different. Thus, the Clean Air Act Amendments of 1990 contained specific mandates requiring OSHA and EPA to establish regulations to protect workplace employees and the public and the environment, respectively. OSHA fulfilled its mandate in 1992 by promulgating the process safety management regulation.

Although NIOSH and OSHA were created by the same Act of Congress, they are two distinct agencies with separate responsibilities. OSHA is in the Department of Labor and is responsible for creating and enforcing workplace safety and health regulations. NIOSH is in the Department of Health and Human Services and is a research agency. NIOSH identifies the causes of work-related diseases and injuries and the potential hazards of new work technologies and practices. With this information, NIOSH determines new and effective ways to protect workers from chemicals, machinery, and hazardous working conditions. Creating new ways to prevent workplace hazards is the job of NIOSH.

A31.1 The Process Safety Management Programme

The fourteen elements of the OSHA Process Safety Management (PSM) regulation (*29 CFR 1910.119*) were published in the federal register on 24 February 1992. The objective of the regulation is to prevent or minimize the consequences of catastrophic releases of toxic, reactive, flammable, or explosive chemicals. The regulation requires a comprehensive management programme: a holistic approach that integrates technologies, procedures, and management practices.

The process safety management regulation applies to processes that involve certain specified chemicals at or above threshold quantities, processes that involve flammable liquids or gases on-site in one location, in quantities of 10,000 lb or more (subject to few exceptions), and processes which involve the manufacture of explosives and pyrotechnics. Hydrocarbon fuels, which may be excluded if used solely as a fuel, are included if the fuel is part of a process covered by this regulation. In addition, the regulation does not apply to retail facilities, oil or gas well drilling or servicing operations, or normally unoccupied remote facilities.

The management system required by OSHA's process safety management regulation envisions a holistic program with checks and balances aimed at creating multiple barriers of protection. The performance-based approach does not prescribe specific methods and approaches, thus giving facilities the flexibility for customizing the methods to best meet their needs and organizational structures. The process hazard analysis (PHA) is the heart of the programme and impacts or interfaces with all of the other elements. However, it must also be pointed out that all elements of the programme must be implemented in their entirety to get the maximum benefit and accomplish the ultimate objective, that is, reduce the frequency and severity of chemical plant accidents. Each element of the process safety programme is discussed in more detail here.

A31.1.1 Employee participation

This element of the regulation requires developing a written plan of action regarding employee participation; consulting with employees and their representatives on the conduct and development of other elements of process safety management required under the regulation; and providing to employees and their representatives access to process hazard analyses and to all other information required to be developed under this regulation.

A31.1.2 Process safety information

This element of the PSM regulation requires employers to develop and maintain important information about the different processes involved. This information is intended to provide a foundation for identifying and understanding potential hazards involved in the process.

The process safety information covers three different areas, that is, chemicals, technology and equipment. A complete listing of the process safety information that must be compiled in these three areas is shown in Table A31.1. This information is intended to provide a foundation for identifying and understanding potential hazards involved in the process.

The information in Table A31.1 is essential for developing and implementing an effective process safety management programme. The fundamental concept is that complete, accurate, and up-to-date process knowledge is essential for safe and profitable operations. The information contained in the first column of Table A31.1 should be available from the Material Safety Data Sheets (MSDS) for the hazardous chemicals, which are used as primary or

Table A31.1 *Process safety information*

Chemicals	*Technology*	*Equipment*
Toxicity	Block flow diagram or process flow diagram	Design codes employed
Permissible exposure limit	Process chemistry	Materials of construction
Physical data	Maximum intended inventory	Piping and instrumentation diagrams
Reactivity data	Safe limits for process parameters	Electrical classification
Thermal and chemical stability data	Consequence of deviations	Ventilation system design
Effects of mixing		Material and energy balances
		Safety systems
		Relief system design and design basis

intermediate feedstocks or are produced as products at the plant.

The information contained in the second column of Table A31.1 pertains to the technology of the process itself. The block flow diagram can be replaced by a process flow diagram. The process chemistry information must contain the basic chemical reactions involved and a brief description of the chemistry involved. The maximum intended inventory refers to the maximum amount of any regulated chemical that may be expected to be present in the whole facility at any time. The safe limits for process parameters refer to the upper and lower bounds for the process parameters outside of which the process would be hazardous. For example, in the case of a distillation process, the upper and lower limits of the process parameters outside which the operation of the process could cause significant damage to the tower or other attached equipment would have to be stated. In this example, the process parameters for which upper and lower bounds are to be specified are temperature, pressure, composition, and flow rate. The consequence of deviation from these stated bounds must also be compiled.

Safe upper and lower limits for process parameters and equipment are also necessary for calibrating instrumentation. It is important to understand the distinction between process parameter limits and equipment limits. Safe upper and lower limits for process parameters can be defined as follows:

(1) For non-reactive processes, process parameter safe limits are defined based on equipment design ratings, relief device setpoints, and upstream and downstream conditions of the process and/or equipment.
(2) For reactive processes, process parameter safe limits are defined based on the process chemistry information or any restricted physical conditions for the reaction as well as the criteria used for non-reactive processes.

In contrast, equipment limits are specified by the manufacturer based on materials of construction and design basis. Processes must be operated and maintained within both the process parameter and equipment limits.

The final type of information that must be compiled pertains to the equipment used in the process. The intent is to assure that all equipment used in the process meets appropriate standards and codes such as those published by the American Society of Mechanical Engineers (ASME), the American Petroleum Institute (API), the American Institute of Chemical Engineers (AIChE), the American National Standards Institute (ANSI), the American Society of Testing and Materials (ASTM), and the National Fire Protection Association (NFPA). Accepted industry practices can be used to decide which standards apply. In cases where standards do not exist, generally acceptable engineering practices can be used. The materials of construction for each equipment item and the design codes employed can be compiled as separate lists or may be listed in the Piping and Instrumentation Diagram (P&ID). The P&IDs must represent the facility exactly as it exists with flanges, valves, and all other connections shown. The different electrical classifications must also be compiled for different parts of the facility. A simple plot plan showing the different areas of electrical classification would be considered to be in compliance with the regulation. Information must also be compiled on any ventilation system. This information would indicate the areas in the facility that are ventilated and the nature of ventilation. A listing of all safety systems must also be compiled that are available to the workers. This listing should include any and all equipment that is available for protection of the workers from any hazard or emergency. Information should also be available on the location of these safety systems and the procedures to use these systems.

As is apparent from the foregoing discussion, compilation of the process safety information database represents a major challenge. This is complicated even more because the process safety information must also be kept up-to-date and accurate and made accessible to employees. Many plants have therefore implemented or are in the process of implementing electronic data management systems to manage, access, and use these data. The completion and accuracy of process safety information is crucial to the implementation of other PSM elements including PHAs and mechanical integrity.

The PSM regulation requires that process equipment should comply with generally accepted engineering practices. It is therefore not only important to compile all equipment information but also to ensure that it complies with consensus standards. OSHA is recognizing that there are consensus standards for design and fabrication, installation, maintenance procedures, and inspection and testing. Therefore, equipment constructed in accordance with codes, standards, or practices no longer in use should be evaluated to ensure that they are compatible with existing standards. For example, a multi-layered vessel built years ago should be evaluated to ensure that it complies with today's engineering standards.

A31.1.3 Process hazards analysis

This element of the PSM regulation requires facilities to perform a PHA. The PHA must address the hazards of the process, previous hazardous incidents, engineering and administrative controls, the consequences of the failure of engineering and administrative controls, human factors, and an evaluation of effects of failure of controls on employees. This element requires that the PHA be performed by one or more of the following methods or any other equivalent method:

(1) what-if;
(2) checklist;
(3) what-if/checklist;
(4) hazard and operability (HAZOP) studies;
(5) failure modes and effects analysis (FMEA);
(6) fault tree analysis.

The regulation suggests a performance-oriented requirement with respect to the PHA so that the facility has the flexibility to choose the type of analysis that will best address a particular process. PHAs may not be performed unless complete Process Safety Information is available for the process.

PHAs and the results of PHAs can and will impact the development, implementation, and practice of other elements of the PSM regulation. A PHA would help facilities identify hazards and ways to address them. PHAs also identify situations where process incidents due to control failure (e.g. pressure gauges, overfill alarms) could be prevented by redundant or backup control or by frequent maintenance and inspection practices.

Many other elements of the PSM program should flow from, or at least be revised based on, the results of the PHA. Existing standard operating procedures, training and maintenance programs, and pre-startup safety reviews may need to be revised to reflect changes in either practices or equipment that derive from the PHA. The PHA may help define critical equipment that require preventive maintenance, inspection, and testing programs. It may also help a facility focus its emergency response programs on the most likely and most serious release scenarios.

The PSM regulation also requires that the PHAs be updated and revalidated, based on their completion date. First, the PSM regulation requires that the PHAs shall be updated and revalidated. Thus, the whole PHA should not only be examined to verify that the PHA is consistent with the current process but it also should be analyzed to examine if the original analysis is valid. Second, the PSM regulation requires that the updating and revalidating be done by a team similar in qualifications to the team that conducted the original PHA. The intent of a PHA revalidation is to ensure that the PHA team evaluates the previous PHA, examines the extent of any changes that might have occurred since the PHA was implemented (or last reviewed) and decide what work is needed to make the PHA current.

A31.1.4 Operating procedures

The operating procedures must be in writing and provide clear instructions for safely operating processes; must include steps for each operating phase, operating limits, safety and health considerations and safety systems. Procedures must be readily accessible to employees, must be reviewed as often as necessary to assure they are up- to-date and must cover special circumstances such as lockout/tagout and confined space entry. The employer must certify annually that the operating procedures are current and accurate. The synergism and commonality of operating procedures to maintenance procedures is in safe work practices. These safe work practices include lockout/tagout, confined space entry, opening of process equipment or piping (i.e. hot tapping), and control of entrance into the battery limits. Even though the operations department is involved with all of these practices, maintenance also plays a very vital role in ensuring that these procedures are followed during all maintenance tasks. Many incidents have resulted from inadequate safe work practices or a failure to follow procedures when they exist.

A31.1.5 Training

The regulation requires that facilities certify that employees responsible for operating the facility have successfully completed (including means to verify understanding) the required training. The training must cover specific safety and health hazards, emergency operations and safe work practices. Initial training must occur before assignment. Refresher training must be provided at least every 3 years.

Even though this element of the PSM regulation pertains to operations staff only, it is important to remember that operations and maintenance training should be coordinated.

A31.1.6 Contractors

The PSM regulation identifies responsibilities of the employer regarding contractors involved in maintenance, repair, turnaround, major renovation or specialty work, on or near covered processes. The host employer is required to: consider safety records in selecting contractors; inform contractors of potential process hazards; explain the facility's emergency action plan; develop safe work practices for contractors in process areas; periodically evaluate contractor safety performance; and maintain an injury/illness log for contractors working in process areas. In addition, the contract employer is required to train their employees in safe work practices and document that training, assure that employees know about potential process hazards and the host employer's emergency action plan, assure that employees follow safety rules of facility and advise host employer of hazards contract work itself poses or hazards identified by contract employees.

A31.1.7 Pre-startup safety review

This element of the PSM regulation requires a pre-startup safety review of all new and modified facilities to confirm integrity of equipment; to assure that appropriate safety, operating, maintenance and emergency procedures are in place; and to verify that a PHA has been performed. Modified facilities for this purpose are defined as those for which the modification required a change in the process safety information.

Usually, changes occur during maintenance and therefore, maintenance personnel should be well versed in pre-startup safety review procedures. Maintenance should ensure that all necessary procedures have been completed prior to start-up.

A31.1.8 Mechanical integrity

This element of the PSM regulation mandates written procedures, training for process maintenance employees and inspection and testing for process equipment including pressure vessels and storage tanks; piping systems; relief and vent systems and devices; emergency shutdown systems; pumps; and controls such as monitoring devices, sensors, alarms and interlocks. The PSM regulation calls for correction of equipment deficiencies and assurance that new equipment and maintenance materials and spare parts are suitable for the process and properly installed.

A31.1.9 Hot work permit

This element of the PSM regulation mandates a permit system for hot work operations conducted on or near a covered process. The purpose of this element of the regulation is to assure that the employer is aware of the hot work being performed, and that appropriate safety precautions have been taken prior to beginning the work. Since welding shops authorized by the employer are locations specifically designated and suited for hot work operations, the regulation does not require a permit for hot work in these locations. Additionally, hot work permits are not required in cases where the employer or an individual to whom the employer has assigned the authority to grant hot work permits is present while the hot work is performed.

A31.1.10 Management of change

This element of the regulation specifies a written programme to manage changes in chemicals, technology, equipment and procedures which addresses the technical basis for the change, impact of the change on safety and health, modification to operating procedures, time period necessary for the change, and authorization requirements for the change. The regulation requires employers to notify and train affected employees and update process safety information and operating procedures as necessary.

A31.1.11 Incident investigation

This element of the regulation requires employers to investigate as soon as possible (but no later than 48 h) incidents, which did result or could have resulted in catastrophic releases of covered chemicals. The regulation calls for an investigation team, including at least one person knowledgeable in the process (a contractor employee, if appropriate), to develop a written report of the incident. Employers must address and document their response to report findings and recommendations and review findings with affected employees and contractor employees. Reports must be retained for 5 years.

A31.1.12 Emergency planning and response

This element requires employers to develop and implement an emergency action plan according to the requirements of *29 CFR 1910.38(a)* and *29 CFR 1910.120(a), (p), and (q).*

A31.1.13 Compliance audits

This element of the regulation requires employers to certify that they have evaluated compliance with process safety requirements every 3 years and specifies retention of the audit report findings and the employer's response. Employer must retain the two most recent audits.

A31.1.14 Trade secrets

Similar to the trade secret provisions of the hazard communication regulation, the PSM regulation also requires information to be available to employees from the process hazard analyses and other documents required by the regulation. The regulation permits employers to enter into confidentiality agreements to prevent disclosure of trade secrets.

A31.2 Summary Comparison of OSHA Elements with CCPS Elements

It is important to point out that the programmes required by OSHA's PSM elements as given in 29 CFR 1910.119 are similar to the requirements of other programme requirements. The comparison matrix in Table A31.2 demonstrates the relevance of OSHA PSM elements to other programmes.

Table A31.2 *Comparison matrix showing the relevance of OSHA PSM elements to other programs*

Appendix 32

Risk Management Program Regulation in the United States

Contents

Environmental issues affecting the public health and the environment also received widespread attention. As a result, the Environmental Protection Agency (EPA) was established in 1970 to protect the nation's public health and environment. The EPA is responsible, 'to find ways to cleanup and prevent pollution, ensure compliance and enforcement of environmental laws, assisting states in environmental protection efforts, and scientific research and education to advance the nation's understanding of environmental issues'. In 1970, the EPA promulgated the Clean Air Act, followed by amendments to the Act in 1977 and 1990.

The Toxic Substances Control Act (TSCA), passed in 1976 gave EPA the ability to track and study the 75,000 industrial chemicals produced or imported to the United States. The TSCA is a federally enforced law and is not delegated to the state. Under this Act, the EPA has the authority to ban the manufacture or distribution in commerce, limit the use, require labelling, or place other restrictions on chemicals that pose unreasonable risk. Asbestos, chlorofluorocarbons, and ploychlorinated biphenyls are some of the chemicals regulated by EPA under TSCA.

> In 1977, the International Safe Container Act established uniform structural requirements for international cargo containers designed to be transported interchangeably by sea and land carriers. In 1983, the Surface Transportation Assistance Act established protection from reprisal by employers for truckers and certain other employees in the trucking industry involved in activity related to interstate commercial motor vehicle safety and health.

In 1990, EPA analysed chemical incidents in the early to mid-1980s and compared them to the Bhopal incident. The analysis concluded that 17 incidents released sufficient volumes of chemicals that could have been more severe than Bhopal if the weather conditions and plant location were different. Thus, the Clean Air Act Amendments of 1990 contained specific mandates requiring OSHA and EPA to establish regulations to protect workplace employees and the public and the environment respectively. OSHA fulfilled its mandate in 1992 by promulgating the process safety management regulation. EPA on the other hand promulgated the Risk Management Program regulation in 1996. The Clean Air Act Amendments of 1990 also established the Chemical Safety and Hazard Investigation Board.

A32.1 The Risk Management Program

In 1996, EPA promulgated the regulation for *Risk Management Programs for Chemical Accident Release Prevention* (40 CFR 68). This federal regulation was mandated by section 112(r) of the Clean Air Act Amendments of 1990. The regulation requires regulated facilities to develop and implement appropriate Risk Management Program to minimize the frequency and severity of chemical plant accidents. In keeping with regulatory trends, EPA required a performance-based approach towards compliance with the Risk Management Program regulation. The eligibility criteria and requirements for the three different program levels are given in Table A32.1.

The EPA regulation also requires regulated facilities to develop a Risk Management Plan (RMP). The RMP includes a description of the hazard assessment, prevention programme, and the emergency response programme. Facilities submit the RMP to the EPA and subsequently is made available to governmental agencies, the state emergency response commission, the local emergency planning committees, and communicated to the public.

The Risk Management Program regulation defines the worst-case release as the release of the largest quantity of a regulated substance from a vessel or process line failure, including administrative controls and passive mitigation that limit the total quantity involved or release rate. For gases, the worst-case release scenario assumes the quantity is released in 10 min. For liquids, the scenario assumes an instantaneous spill and that the release rate to the air is the volatilization rate from a pool 1 cm deep unless passive mitigation systems contain the substance in a smaller area. For flammables, the scenario assumes an instantaneous release and a vapour cloud explosion using a 10% yield factor. For alternative scenarios (note: EPA used the term *alternative scenario* as compared to the term *more-likely scenario* used earlier in the proposed regulation), facilities may take credit for both passive and active mitigation systems.

Appendix A of the final regulation lists endpoints for toxic substances to be used in worst-case and alternative scenario assessment. The toxic endpoints are based on ERPG-2 (Emergency Response Planning Guidelines – Level 2) or level of concern data compiled by EPA. The flammable endpoints represent vapour cloud explosion distances based on overpressure of 1 psi or radiant heat distances based on exposure to 5 kW/m^2 for 40 seconds.

Similar to OSHA's PSM regulation, coverage under the the EPA risk management program regulation is determined by a list of chemicals with associated threshold quantities. However, in contrast to the OSHA PSM regulation, the EPA Risk Management Program regulation prescribes a tiered programme based on the risk and incident history of the facility. In order to determine coverage and compliance requirements, a facility may follow the steps described below in chronological order:

(1) Check the EPA Risk Management Program list of chemicals to determine if any of the chemicals are present on site above the listed threshold quantity at any time. The threshold quantity determination is not cumulative, but the maximum that could be present on site at any given time. Other considerations that may enter into the threshold quantity determination are proximity, interconnectivity, concentration, etc. EPA also provides rules for mixtures and effect of dilution. If threshold quantity is not exceeded, then the facility is not subject to the EPA risk management program, and steps 2–4 need not be completed.

(2) If any of the listed chemicals are present at or above the listed threshold quantity, the facility must perform a worst-case scenario analysis. If the impact zone from worst-case scenario does not contain any public receptors, the facility has had no incidents in the last 5 years, and the facility's emergency response plan is coordinated with local emergency response officials; then the facility belongs in Program 1.

(3) If the facility can not claim coverage under Program 1 and the facility is classified in any of the industrial classification codes listed in Table A32.1 or the facility is covered by the OSHA PSM regulation, then the facility belongs in Program 3 and must comply with Program 3 requirements.

(4) If the facility does not belong in Program 1 or Program 3, then by default the facility is required to comply with Program 2 requirements.

Table A32.1 *Eligibility criteria and compliance requirements for different program levels – EPA's Risk Management Program regulation*

Program 1	*Program 2*	*Program 3*
Program Eligibility Criteria		
No offsite accident history No public receptors in worst-case circle Emergency response coordinated with local responders	Process not eligible for program 1 or 3	Process is subject to OSHA PSM (29 CFR 1910.119) Process is SIC code 2611, 2812, 2819, 2821, 2865, 2869, 2873, 2879, or 2911
Program Requirements		
Hazard assessment	*Hazard assessment*	*Hazard assessment*
Worst-case analysis	Worst-case analysis	Worst-case analysis
5-year accident history	Alternative releases	Alternative releases
Certify no additional steps needed	5-year accident history	5-year accident history
	Management program	*Management program*
	Document management system	Document management system
	Prevention Program	*Prevention Program*
	Safety information	Process safety information
	Hazard review	Process hazard analysis
	Operating procedures	Operating procedures
	Training	Training
	Maintenance	Mechanical integrity
	Incident investigation	Incident investigation
	Compliance audit	Compliance audit
		Management of change
		Pre-startup safety review
		Contractors
		Employee participation
		Hot work permits
	Emergency response program	*Emergency response program*
	Develop plan and program	Develop plan and program

As stated earlier, EPA used a tiered approach based on risk and the facility's incident history. It is a recognition of the fact that one size does not fit all and the risk management program is based on a three-pronged approach. First, the hazard assessment provides information about potential off-site consequences and the incident history of the facility. The prevention programme and the emergency response programme are then developed based on the hazard assessments. It should be noted that the prevention programme requirements under Program 3 mirror the OSHA PSM programme requirements.

Appendix 33

Incident Databases

Contents

Accident prevention and mitigation of consequences is the focus of a number of industry programmes, regulatory initiatives. As part of these programmes and regulations, accident history data is often collected. There are two basic types of information. One is a database consisting of standardized fields of data usually for a large number of incidents. The second are more detailed reports of individual incidents.

Analysis of these accident history databases can provide insight into accident prevention needs. While the analysis and conclusions obtained from the accident database is often limited by the shortcomings of the databases themselves, the fact remains that accident history databases are very useful and can be a powerful tool in focusing risk reduction efforts. The conclusions can be used to systematically identify the greatest risks to allow prioritization of efforts to improve process safety. At the plant level this might entail identifying certain processes, types of equipment, chemicals, operations and other factors most commonly associated with incidents. Databases that cover a very large number of facilities are likely to reveal trends and patterns that no one company or facility could determine from their own experience.

Statistical knowledge of the likelihood of the release of certain types of chemicals could help emergency responders, state emergency response commissions, and local emergency planning committees determine the most likely and most serious chemical releases in their areas and plan appropriate chemical accident responses.

Incident databases may also help identify technologies and practices to prevent chemical accidents, or the need to develop them. For example, the data could indicate that inspection and preventive maintenance of equipment and instruments should become more thorough or more frequent.

The Mary Kay O'Connor Process Safety Center (MKOPSC) provides an assessment of the usefulness of US Federal databases in *Feasibility of Using Federal Incident Databases to Measure and Improve Chemical Safety.* This study identifies a number of trends and patterns of chemical incidents. It also makes a number of recommendations for improving these databases. The report defines an incident as, "An incident is the sudden unintended release of or exposure to a hazardous substance, which results in or might reasonably have resulted in, deaths, injuries, significant property or environmental damage, evacuation or sheltering in place." This definition will be used as a reference to describe the type of incidents reported in the following section.

A33.1 Incident Databases

A33.1.1 National Response Center (NRC) Incident Reporting Information System (IRIS)

The NRC is the primary initial notification system for the US federal government. It is operated 24 h a day, 7 days a week. It receives the notification of a release and forwards that information to numerous federal, state and local agencies. Approximately 25,000 incidents are reported each year. However, the majority of these incidents involve very small or unknown quantities. While reporting to the NRC is required by a number of statutes, it also receives numerous 'complaints' from the public. Many of the incidents are spills of fuel from motor vehicles, small spills of low hazard materials such as lubricating oil and oil sheens on water with unknown sources, quantities and effects. Only about 30% of the reported cases constitute an incident as defined in the MKOPSC report.

Because this system contains initial reports the information is preliminary and many times inaccurate or incomplete. There is also duplicate reporting of incidents. The completeness and accuracy of chemical names depends on the knowledge level of the person reporting the incident. It has been found that those reports from chemical manufacturing facilities are more accurate and do provide useful information. For a limited number of incidents, NRC also presents a limited number of detailed incident summaries.

A33.1.2 EPA Risk Management Plan (RMP) – 5-year accident history

The US EPA as part of its Risk Management Program requires certain facilities to report their 5-year accident history. This requirement applies to releases of a listed substance that is stored above a threshold quantity and results in fatalities, injuries, or significant environmental or property damage. The initial 5 years covered the period from mid-1993 to 1998.

Only 1900 releases are reported from about 14,500 facilities for the 5-year period. The combination of the three main reporting criteria appears to exclude a large number of incidents. The reports do address such items as the causes and consequences of the release and steps taken to prevent or mitigate future incidents. Since the reporting is from a defined universe of facilities it allows statistical treatment of the frequency of releases not available from systems that report releases from an undefined universe of facilities.

A33.1.3 Agency for Toxic Substances Disease Registry (ATSDR) – Hazardous Substances Emergency Events Surveillance (HSEES)

The ATSDR administers a programme with approximately 15 states to collect information regarding chemical releases and their health effects on workers, emergency responders and the public. This database now contains over 50,000 events and adds more than 5000 per year. This is probably the largest high quality dataset in existence. Releases from both fixed facilities and transportation systems are included. The reporting excludes releases of petroleum products unless they contain other hazardous materials. This system focuses on the health effects that are gatheredfrom numerous sources such as public records, hospitals, media and interviews. The database is expected to be available to the general public by the time this handbook is published. The agency issues annual reports summarizing the results. These reports generally exclude some details such as the quantity released that would be helpful in the analysis of incidents. However, such information will be available when the database is released.

A33.1.4 EPA Accidental Release Information Program (ARIP)

This discontinued program contains nearly 5,000 incidents collected primarily in a 3-year period in the late 1980s. Prior to the establishment of other programmes in the 1990s this was one of the best sources of data. While there was no strict criteria for reporting to this database it is one of the larger collections of incidents with details concerning, causes, consequences, operating mode, and corrective actions. Facilities reported in response to a request from the

EPA. Requests were sent to facilities that reported frequent or significant incidents. While no trends can be gathered from this system it does provide detailed information not available in other systems. The database generally excludes releases of simple hydrocarbons.

A33.1.5 Accident Investigation System (AIS) – Occupational Safety and Health Administration, US Department of Labor

This system contains reports from all OSHA-regulated facilities with accidents resulting in a fatality or three or more injuries. The most useful feature of the system is that it includes a brief description of how the incident occurred. Most systems lack this feature making it very difficult to determine what actually occurred during an incident. Also, there are no arbitrary limits on the type of chemical involved or its quantity, only on the consequences. This database contains many accidents unrelated to chemicals but does include a text search.

A33.1.6 US Department of Transportation (DOT) – Hazardous Material Incident Reporting System (HMIRS)

This reporting system includes all modes of transportation except pipelines. Reporting is required from all interstate transport companies and results in a total of about 17,000 reports per year. Like the NRC, many of these cases are of little significance and do not meet the definition of an incident in the MKOPSC report.

A33.1.7 US DOT Integrated Pipeline Information System (IPIS)

Pipelines are covered in three categories, one for natural gas distribution, one for natural gas transmission and one for all other hazardous substances.

A33.1.8 Center for Chemical Process Safety (CCPS)

CCPS maintains a private database. Only members that contribute incidents to the database are allowed to view the data.

A33.1.9 Major Accident Hazards Bureau (MAHB), Major Accident Reporting System (MARS)

This system is maintained by the European Union's MAHB. It is a hybrid between a database and a report-based system. While the data is structured it contains extensive text descriptions of the incidents. The data is sanitized to remove identifying references. There are currently about 400 cases available to the public.

A33.2 Injury and Fatality Databases (Not Tied to Specific Incidents)

The following are sources of statistical information regarding injuries and fatalities due to chemicals. They do not reveal the details of specific incidents but do provide statistical information about injuries due to chemicals in the United States.

A33.2.1 Occupational Illness and Injury Statistics (OIIS) – Occupational Safety and Health Administration, US Department of Labor

These statistics are based on an annual sampling of about 250,000 companies in the United States. This data has been collected and reported on a consistent basis since 1992. There is good detail for chemicals and industries involved in injuries. There are additional details concerning the type of injury and the body parts involved.

A33.2.2 Census of Fatal Occupational Injuries (CFOI) – Occupational Safety and Health Administration, US Department of Labor

Beginning in 1992, OSHA implemented a rigorous system of counting all fatal occupational injuries. This is based on cross checking at least two sources of information. This system also contains the chemical and industry involved. The OSHA web site features both a querying system as well as formatted tables of data.

A33.2.3 Mortality Database, Centers for Disease Control, United States

This system is based on an analysis of all death certificates in the United States. It therefore includes all commercial, transportation and residential settings. The system also includes intentional acts such as assaults, suicides and substance abuse, which are not normally considered to be chemical incidents.

US death certificates are coded to indicate the cause of death. There is also a set of codes that describe the source of injury if applicable. A variety of codes describe hazardous substances.

A33.2.4 US Coast Guard (USCG)

The USCG maintains a database of oil spills and another for chemical spills to navigable waters. The incidents are typically those observed by the Coast Guard. The vast majority involve small or unknown quantities. The data show clear progress in reducing the quantity of oil spilled over the last 30 years.

A33.2.5 National Electronic Injury Surveillance System – Consumer Product Safety Commission, USA

This system is based on data from the emergency rooms of approximately 100 US hospitals. These hospitals are chosen to reflect US demographics. Specific events are not reported to maintain patient confidentiality. Statistical information for chemical related injuries are reported.

A33.3 Incident Investigation Reports

A33.3.1 United States

United States Chemical Hazard and Safety Board (CSB)

The CSB is the primary investigatory body for fixed facility chemical accidents. They perform detailed examinations of major accidents. They also perform studies of various classes of accidents such as reactive chemicals.

United States Department of Energy

The DOE has an on-line database of Red Alerts, Yellow Alerts, Lessons and Good Work Practices. These mainly involve the contractors that operate various DOE facilities.

United States Environmental Protection Agency (EPA)

The EPA performed several investigations before the advent of the CSB.

United States Fire Administration (USFA)

The USFA investigates major fires of all types. About a dozen of these reports cover chemical incidents.

National Institute for Occupational Safety and Health (NIOSH)

The National Institute for Occupational Safety and Health (NIOSH) Fatality Assessment and Control Evaluation

(FACE) programme is a research programme designed to identify and study fatal occupational injuries. The goal of the FACE programme is to prevent occupational fatalities across the nation by identifying and investigating work situations at high risk for injury and then formulating and disseminating prevention strategies to those who can intervene in the workplace.

The FACE programme currently has two components:

(1) NIOSH in-house FACE began in 1982. Participating states voluntarily notify NIOSH of traumatic occupational fatalities resulting from specific causes of death that have included *confined spaces*, electrocutions, machine-related, falls from elevation, and logging. The confined space incidents are the ones of interest in terms of process safety. In-house FACE is currently not targeting confined space incidents.
(2) NIOSH State-based FACE began in 1989. Currently, 15 State health or labour departments have cooperative agreements with NIOSH for conducting surveillance, targeting investigations, and recommending prevention activities at the State level using the FACE model.

There are approximately 75 NIOSH reports and 70 state reports.

NIOSH has also published a series of 'Fire Fighter Fatality Investigation Reports'. Several of these are chemical related incidents.

Occupational Safety and Health Administration (OSHA)

OSHA, sometimes in collaboration with the EPA, investigated several incidents before the creation of the CSB.

National Transportation Safety Board (NTSB)

The NTSB has responsibility for investigating transportation related hazardous materials spills on highways, airlines, railroads and pipelines. NTSB classifies incidents as Hazardous Materials Accidents for all modes of transportation except pipelines. Pipeline Accident reports are listed separately. Maritime incidents are excluded, they are handled by the USCG.

The Pipeline Accident reports include about 17 incidents since 1994 which are on-line and 69 reports prior to that time which are available on paper. The Hazardous Materials Accident reports include 18 since 1998 that are on-line and 55 available on paper.

Minerals Management Service (MMS)

The MMS investigates incidents related to offshore drilling activities. In-depth reports are called 'Accident Investigation Panel Reports'. Approximately 25 of these are related to pipeline leaks, fires, explosions or blowouts.

Department of Labour – Mine Safety and Health Administration (MSHA)

The MSHA reports include approximately 20 incidents involving fatalities that meet the criteria of chemical incident. The incidents of interest are generally classified as 'Ignition or Explosion of Gas or Dust' or 'Exploding Vessels Under Pressure'.

National Fire Protection Association (NFPA)

The NFPA has produced 141 detailed fire investigations. These reports are available on-line. They are free of charge to NFPA members. Paper copies are available for purchase. Approximately 15 of the reports are chemical related incidents.

A33.3.2 Australia

Australian Transport Safety Bureau (ATSB)

The ATSB have produced 16 reports of interest. These are primarily related to engine room fires on ships.

Department of Mineral and Petroleum Resources (Western Australia)

The DMPR has produced 10 reports of interest concerning a variety of topics.

Victorian Work Cover Authority

Various reports and guidance are found in 'Alerts & Guidance Notes'.

A33.3.3 Canada

Alberta Energy and Utilities Board

The AEUB has produced several incident reports as well as studies related to the hazards of sour natural gas.

Workplace Health and Safety, Alberta

They have produced about 16 reports concerning various fires, explosions and exposures. The reports under the heading 'Fatality Reports' cover the period from 1997 to 2002.

Canadian Center for Occupational Health and Safety (CCOHS)

The CCOHS has produced approximately 60 reports mostly covering fires and explosions. Fatality Reports contains information about the circumstances surrounding occupationally related fatalities. Information is extracted from reports on inquests and inquiries into occupationally related fatalities across Canada. These reports may be from Coroners, Medical Examiners, Government Ministries, or any other body responsible for inquiry into occupational fatalities.

Database highlights are:

(1) unique safety database identifies unsafe equipment, practices, work conditions;
(2) inquest reports offer practical recommendations to prevent recurrences of fatalities.

Transport Safety Board of Canada (TSB)

The TSB is quite similar to the NTSB in the United States. Their interest is in identifying causes and recommending solutions. They do not have regulatory authority. Approximately 45 rail incidents, 14 pipeline incidents and 7 marine incidents involve hazardous materials are available. The reports are under the headings Pipeline, Marine and Rail on theirwebsite.

A33.3.4 Finland

Finland Accident Investigation Board (English summary)

The FAIB has produced 16 reports covering Rail, Maritime and Fixed facilities. Their website contains English summaries that are about one page. The actual reports in Finnish are much more detailed.

A33.3.5 United Kingdom

Health and Safety Executive

MHIDAS (Major Hazard Incident Data Service) is a database of incidents involving hazardous materials that had an off-site impact, or had the potential to have an off-site impact. Such impacts include human casualties or damage to plant, property or the natural environment.

MHIDAS is maintained by, AEA Technology plc on behalf of the UK Health and Safety Executive, and features:

(1) searchable codified and textual information on more than 11,000 incidents, involving the transportation, storage and processing of hazardous materials;
(2) worldwide coverage, with a focus on incidents occurring in the United Kingdom and United States;
(3) comprehensive coverage of incidents that have occurred during the last twenty years, plus significant earlier incidents;
(4) new data made available on a quarterly basis.

Each MHIDAS incident is coded in a standard format to include details such as:

(1) the hazardous material involved in the incident;
(2) the number of fatalities, injuries and evacuations attributable to the incident;
(3) a brief description of the circumstances of the incident.

Information from MHIDAS can be accessed:

(1) through a personalized service, provided on a fee basis through AEA Technology, or
(2) on a subscription basis, via CD-ROM or Internet, or
(3) via an on-line information Retrieval Service, for which charges are made.

Marine Accident Investigation Branch (MAIB)

The MAIB has produced seven relevant detailed reports and nine articles in their monthly “Safety Digest”. The fundamental purpose of investigating an accident under these regulations is to determine its circumstances and the causes with the aim of improving the safety of life at sea and the avoidance of accidents in the future. It is not the purpose to apportion liability, nor, except so far as is necessary to achieve the fundamental purpose, to apportion blame.

Appendix 34

Web Links

Contents

A34.1 General Information

Safety Information and the Internet, http://hazard.com/course/

The site provides general information on how to use the internet as a tool to obtain required information.

A34.2 Technical Information

Government Research Center, NTIS search engine, http://grc.ntis.gov/

The National Technical Information Service (NTIS) database offers unparalleled bibliographic coverage of research sponsored by the United States and selected foreign governments.

Risk World – First Internet Chemical Process Safety Business Portal, http://www.riskworld.com

This site has a comprehensive source of risk related information on all aspects of life – chemicals, bioterrorism, business, safety, etc.

Risk Analysis Methodologies, http://home1.pacific.net.sg/~thk/risk.html

The site is maintained by T.H. Keong and provides an overview of risk assessment methods.

Root Cause Analysis, http://www.rootcauselive.com/

A website devoted to root cause analysis practitioners.

A34.2.1 Energetic materials/reactive chemicals

Chemweb – Brethericks Databases, http://chemweb.com/databases/brethericks

Bretherick's database is a comprehensive source of information on energetic or reactive materials.

Explosion Hazards Database – National Institute of Materials and Chemical Research (NIMC), http://www.aist.go.jp/RIODB/db005/index.html

This database includes explosion hazard test data for energetic materials obtained at laboratories of the NIMC in Japan.

UK Chemical Reaction Hazard Forum, http://www.crhf.org.uk/

UK Chemical Reaction Hazards Forum is a group of process safety professionals from the UK chemical industry for mutual exchange of information, expertise and ideas

A34.2.2 Toxicology

Environmental Defense Fund – Chemical Scoreboard, http://www.scorecard.org/

Scorecard is a source for free and easily accessible local environmental information. One can learn about environmental issues in your community by typing in zip code. Scorecard carries health and environmental related information for the chemicals in its database.

National Toxicology Program, http://ntp-server.niehs.nih.gov/

National Toxicology Program (NTP) coordinates toxicological testing programmes within the Department of Health and Human Services, strengthens the science base in toxicology; develops and validates improved testing methods; and provides information about potentially toxic chemicals to health regulatory and research agencies, the scientific and medical communities, and the public.

NIOSH – Registry of Toxic Effects of Chemical Substances (RTECS), http://www.cdc.gov/niosh/rtecs.html

RTECS, maintained by National Institute for Occupational, Health, and Safety (NIOSH) is a compendium of data extracted from the open scientific literature. Six types of toxicity data are included for a chemical: (1) primary irritation; (2) mutagenic effects; (3) reproductive effects; (4) tumorigenic effects; (5) acute toxicity; and (6) other multiple dose toxicity.

A34.3 University Academic Programmes

Fire Protection Engineering Program, University of Maryland, College Park, http://www.enfp.umd.edu/

The programme offers fully accredited undergraduate program and one of two graduate degree programs in the Unitied states.

Hazard Lab Group, Michigan Tech University, http://www.chem.mtu.edu/org/hazards/hazards.html

The research of the group members focuses on generating data for flammable and reactive compounds.

Mary Kay O'Connor Process Safety Center (MKOPSC), Texas A&M University, http://process-safety.tamu.edu

The research of the center focuses on process safety in the chemical industry.

Safety, Environment and Loss Prevention, Chemical Engineering Department, Loughborough University, http://www.lboro.ac.uk/departments/cg/research.html

The research of the group focuses on sustainable process development.

Thermal Hazards Laboratory, Queens University, http://me.queensu.ca/people/birk/research/thermalHazards/

The focus of the research at the Thermal Hazards Laboratory is the safety of the storage and transportation of pressure liquified gases. The laboratory uses large scale experiments and thermodynamic modelling to study the response of a vessel in an accident situation and the possible hazards arising from vessel failure.

A34.4 Government Organizations

Health and Safety Executive (HSE), http://www.hse.gov.uk/

The UK Health and Safety Commission (HSC) and the Health and Safety Executive (HSE) are responsible for the regulation of almost all the risks to health and safety arising from work activity in Britain.

Environmental Protection Agency (EPA), http://www.epa.gov

EPA provides leadership in the nation's environmental science, research, education and assessment efforts. The Agency also works with industries and all levels of government in a wide variety of voluntary pollution prevention programmes and energy conservation efforts.

Occupational, Safety and Heath Administration, http://www.osha.gov

OSHA's mission is to prevent work-related injuries, illnesses, and deaths.

US Chemical Safety Board (CSB), http://www.chemsafety.gov/

The mission of the US Chemical Safety and Hazard Investigation Board is to promote the prevention of major chemical accidents at fixed facilities.

A34.5 Societies, Councils, Institutes

American Industrial Hygiene Association (AIHA), http://www.aiha.org/

AIHA promotes, protects, and enhances industrial hygienists and other occupational health, safety and environmental professionals in their efforts to improve the health and well being of workers, the community, and the environment.

Center for Chemical Process Safety (CCPS), http://www.aiche.org/ccps/

CCPS brings together manufacturers, insurers, government, academia, and expert consultants to lead the way in improving manufacturing process safety.

Institute of Chemical Engineers (IChemE), http://www.icheme.org

IChemE is a leading international body, providing services for and representing the interests of those involved in chemical, biochemical and process engineering worldwide.

A34.6 Security and Vulnerability Assessment

American Chemistry Council (ACC) Site Security Guidelines, http://www.responsiblecaretoolkit.com/

ACC offers Guidelines for the U.S. Chemical Industry, developed by a group of company security professionals and designed specifically for the chemical industry, can help member companies build upon their existing security programmes.

CCPS Security and Vulnerability Analysis (SVA), http://www.aiche.org/ccps/sva/

CCPS recommends a method for industry to analyse their chemical security risks.

Sandia National Laboratory's, http://www.nlectc.org/ccfp/

Center for Civil Force Protection (CCFP) at Sandia National Laboratories (SNL) provides physical security counter terrorism assistance to state and local agencies.

References

Notes

(1) References are given in the text by surname only, except where there would be ambiguity, in which case the initials are given also.
(2) References for which no date has been established are denoted (n.d.) and head their group alphabetically. Where the approximate date is known, this is indicated, e.g. SMITH, J. (*c.* 1988).
(3) Anonymous entries are grouped at the start of the references and are in date order.
(4) In ranking a name alphabetically, elements such as de or von are disregarded, e.g. von Bismark is listed under B rather than V.
(5) Chinese names are given in the form used by the particular author, i.e. either in full or by surname with initials.
(6) The following abbreviated titles are used:

Abbreviated title	*Full title*
Ammonia Plant Safety, **1**–	*Safety in Air and Ammonia Operations Prog.s*, 1960, Vol. 2– (*Ammonia Plant Safety and Related Facilities*), 1970, Vol. 12– (both New York: Am. Inst. Chem. Engrs)
Carriage of Dangerous Goods, **1**	*Carriage of Dangerous Goods 1*
Chemical Process Hazards **1**–	*Chemical Process Hazards with Special Reference to Plant Design*, 1960, **I**-; then Hazards IX, 1986, IX- (both London, then Rugby: Inst. Chem. Engrs)
Combustion, **1**–	*Symp. on Combustion*, 1928, **1**; 1937, **2** (both Pittsburgh, PA: Combustion Inst.); 1949, **3**; 1953, **4** (both Baltimore, MD: Williams & Wilkins); 1955, **5**; 1957, **6** (both New Tork: Reinhold); 1959, **7** (London: Butterworths); 1960, **8** (Baltimore, MD: Williams & Wilkins); 1963, **9** (New York: Academic Press); 1964, **10**; 1967, **11**; 1968, **12**; 1970, **13**; 1972, **14**; 1975, **15**; 1977, **16**; 1979, **17**; 1981, **18**; 1982, **19**; 1985, **20**, 1988, **21**; 1989, **22**; 1990, **23**; 1991, **24** (all Pittsburgh, PA: Combustion Inst.)
Control of Hazardous Material Spills, **1**–	*Nat. Conf. on Hazardous Material Spills*, 1971, Houston, TX; 1974, Fransisco, CA; 1976, New Orleans, LA; 1978, 4, Miami Beach, FL; *Nat. Conf on Hazardous Material Spills*, 1980, Louisville, KY; 1986; 1988, Chicago, IL
